METHODS OF LOCALIZATION OF SPINAL TUMORS WITH REFERENCE TO THEIR MEDICAL AND SURGICAL TREATMENT.*

By E. CASTELLI, M.D.,

NEW YORK.

CONSULTING PHYSICIAN TO THE COLUMBUS HOSPITAL; ATTENDING NEUROLOGIST TO THE POST-GRADUATE SCHOOL; ATTENDING NEUROLOGIST TO THE NEUROLOGICAL HOSPITAL.

WHEN we say spinal tumor and want to keep to the exact meaning of the expression we should only consider those tumors derived from the medullary axis itself, that is to say, intramedullary tumors. But this would be too narrow a conception, and therefore under the term "tumors of the spine" we must include all the new formations developed inside and around the spinal cord and revealing their presence from a clinical standpoint by a whole series of symptoms greatly resembling each other.

So, under this chapter of spinal tumors, we will include the tumors of the meninges, the tumors which are developed in the epidural space at the expense of the fatty matter or vessels contained in it, and even the tumors originating in the prevertebral region of the neck, in the thorax, or in the abdomen, in the last instance the tumors having ultimately penetrated this cavity. The bony tumors which have developed at the expense of the vertebræ and which are by certain writers classified in the same group, should, it seems to me, be put in another division and need only be studied for purposes of diagnosis.

Consequently the rational classification to be adopted is the following: (1) Spinal tumors, properly called, which have developed in the interior of the medulla. (2) Tumors of the meninges, involving the dorsal or visceral surface of the pia mater, arachnoid or dura mater. (3) Tumors which have developed at the expense of the morphological elements and tissues contained in the epidural space, the fat, the vessels, and the fibrous tissue. (4) Tumors coming from the outside and penetrating the epidural space through the foramina vertebralis.

This division is a perfectly rational one, being based on the genesis of the tumor, but is sometimes too schematic for clinical purposes. In taking this point of view, which is a most important one for the practitioner, we must restrict our classification to two types which are very different in their symptomatology, evolution, prognosis, and possibility of intervention. These types are first extramedullary tumors and second, intramedullary tumors. It may be stated at the outset that those belonging to the first class are the more interesting to study, since they can be exactly diagnosed at an early stage, and since they can be operated upon. We shall see that by careful study of their symptomatology and with the aid of recent discoveries one can arrive in most cases at a precise diagnosis of these extramedullary tumors and recognize if they are developed outside or inside the dura mater; this is an important point since the prognosis in the case of surgical intervention is singularly better in extradural tumors.

The etiology naturally varies according to the seat of the tumor. Of course it is understood that in the description of these different types I shall speak only of the primary tumors, because the metastatic tumors, either medullary or meningeal, which are not exceptional, represent the type of neoplasm from which they originate; such are epitheliomata of the breast, of the lungs and, above all, of the stomach.

A. Intramedullary Tumors.—These are rare and their types are the following: (1) *Glioma.* The infiltrating glioma sometimes spreads over a large surface of the cord and increases its diameter. It is a single tumor. The neoplastic tissue has characteristic morphological elements, which consist of numerous fibrillæ which do not anastomose, but form a network and neuroglia fibrillæ, with a predominance either of the cells or of the fibrillæ. This neoplastic tissue invades the medulla, destroys indiscriminately white and gray matter, and sometimes bulges at the periphery of the medulla. Under the term gliosis is described the proliferation of neuroglia similar to that present in syringomyelia, in which there is a central gliomatous mass, which secondarily and gradually forms the characteristic cavity of syringomyelia. This formation does not give the symptomatology of spinal tumors, and consequently will not be included under this classification. (2) *The tubercles.*—The Spinal tubercle may be single (solitary tubercle) or multiple, but it is very rare. Very often the tuberculous tumor of the cord is associated with tuberculosis of the spinal bulb, midbrain, cerebellum, and cerebrum. The tubercles are formed by short, round masses which, because of their centrifugal development, produce an increase in the volume of the cord, which is sometimes double in volume in the region occupied by the tubercle. The development of the tumor takes place in the center of the cord. Its substance is pushed toward the periphery and sometimes reduced to the size of a very thin layer of nervous tissue. Notwithstanding this apparently enormous destruction of tissue, there is sometimes more than a destruction; there is a displacement of the different elements of the cord. Very often the tubercle develops itself on the half of the medullary segment in which it is located. The tubercle can grow in any part of the spinal cord, but it is most frequently found at the lower end. (3) *Fibroma, neurofibroma,* and *fibrosarcoma* are very

*Read before the Academy of Medicine, Section of Neurology, on January 14, 1913.

rare as intramedullary tumors. There are sharply defined growths central or peripheric, most frequently associated with tumors of the cranial nerves, of the roots and of the peripheral nerves. They constitute the so-called diffused neurofibrosarcomatosis (von Recklinghausen's disease.)

B. Tumors of the Meninges.—(1) *Fibromata* are frequent but rarely pure, being mostly associated with sarcoma or with myxoma. They include fibrosarcoma, fibromyxoma, and fibromyxosarcoma. They are more frequently intradural, and arise from the dura mater and delicate membranes or from nerve roots. The solitary fibroma is not larger than a plum stone. It is firm and grows slowly. It is not adherent to the dura mater, but is generally attached to it by a small vascular ligament. It develops very often at the posterior surface of the cord or on the side between the anterior and posterior roots, which it presses and distends. In multiple fibroma (neurofibroma) very often the peripheral nerves, the spinal nerve roots within or outside the dura mater, and the cauda equina are affected. Sometimes the tumor invades the cord. Once taken out these tumors do not recur. Most probably they are congenital malformations. (2) *Angiosarcoma,* psammoma, endothelioma, and psammomatous endothelioma are terms applied to the same variety of tumors and all are equally frequent. They are not perfectly round growths, but are lobulated new formations, independent of the cord and dura mater and very often adherent to the roots and vessels. They develop very slowly, generally commencing in the inner surface of the dura mater, and often compressing the cord without invading it. The histological structure consists of small, flat cells, which often have a concentric arrangement with very little intercellular tissue, but with numerous round masses which become very strongly stained and around which the cells are disposed in concentric layers. These masses are considered by some pathologists as old vessels, which explains the term angiosarcoma, but these growths should be regarded as formations identical with those of the epidermic globules. So it is preferable to call them psammomatous endotheliomata. (3) *Neurofibrosarcoma,* which has been already referred to in the case of the intramedullary tumors, are multiple tumors and are disposed on the roots and on the cauda equina. They are very rare, do not give the real symptoms of spinal tumors, and cannot be operated upon because they are multiple. (4) *Sarcomata* are found very seldom as pure sarcoma on the soft meninges; more frequently they are tumors of the dura mater, especially developed on the external surface. Very seldom a well defined new formation, it invades the layers of the dura mater without traversing it, and reaches its interior surface. The round cells are pressed together and separated by fibrous membranes and adhere to the dura mater, forming masses which cover the dura mater over a large area and all around it with a predominance on the posterior surface. These masses cover also the roots and in some cases pass with the ganglia through the vertebral foramina. The fascicular sarcoma of the nerve roots grows slowly, causes no metastatic growths, and usually does not invade the cord, but affects it only by compression. (5) *Lipoma* is very seldom pure, is more frequently constituted by a deposit of fat around the tumors of vascular origin (angiolipoma, fibrolipoma) and is generally developed in the epidural space. It forms an elongated growth, sometimes from two to five inches in length, and can develop also in the interior of the dura mater and only exceptionally in the cord. In this case there is a deposit of fat around the old lesions of phlebitis, arteritis, and meningitis. (6) *Angiomata* and hemangiomata are seen frequently in the soft meninges and are associated with the fibroma (Flatau.) (7) Neurofibroangioma cavernosus are apparently classed with the fibromata. The only important difference is the development of the vessels. As regards the presence of nerve fibers these are probably fibers pertaining to the roots which are placed at the surface of the tumors. (8) The *other variety* of tumors sometimes observed include the osteomata myomata and enchrondromata, which are only exceptionally found.

Pathological Anatomy.—I shall not enter into histological details of which I have sufficiently spoken. I shall not describe in detail the meningitic and medullary lesions caused by tumors, but shall refer only to the important facts from a clinical point of view. The principal difference between the lesions caused by intra- and extramedullary tumors are as follows: (a) In the case of intramedullary tumors the growth in developing dissociates and presses on the different anatomical elements forming the medulla and destroys them. The gray matter being particularly frail is the first to be affected by the growth, but in the majority of cases these tumors develop in the center of the cord and arrive only secondarily at the periphery. They often destroy one-half of the medulla, giving rise to a Brown-Séquard syndrome. But it is to be noted that tubercles often do not destroy so much as press together and push the different constituting anatomical elements of the medulla towards the periphery, while as a rule in intramedullary tumors the lesions of the white and gray matter are destructive. It is the contrary in the case of extramedullary tumors. These destructive lesions manifest themselves in the degeneration of the descending column below the seat of the tumor (lateral column, crossed pyramidal tract) and of the ascending column above the tumor (Goll's and Burdach's columns, direct cerebellar tract and tract of Gowers). These destructive lesions are accompanied by edema in the compressed part of the cord; the nerve sheaths at the periphery of the tumors are swollen thrice in volume forming voluminous non-colored sheaths. These phenomena precede the phenomena of destruction.

(b) In the case of extramedullary tumors the destructive lesions are exceptional, and can only be seen when the very voluminous neoplasm has evolved during a period of many years. It is not rare to observe that a cord after a compression lasting five or six years presents nothing else than a deformation, sometimes very marked, with slight marginal demyelinization. Notwithstanding that the spastic frequently intense paraplegia is accompanied by contraction in flexion, the degeneration of the motor columns is never found. What we generally find is: (1) A deformation of the medulla, generally lateral or posterolateral, the cord being compressed in one point by the tumor. (2) Edematous lesions which are sometimes very considerable, the nerve fasciculæ being swollen and transparent with the sheath sometimes partially demyelinized, at the level of the compression. (3) Marginal demyelinization spreading over the whole length of the medulla and having its

maximum at the level of the compression is not peculiar to tumors and is seen in all forms of compression, for instance, in pachymeningitis. The meninges are generally but slightly touched, the pia mater being sometimes slightly thickened. In cases

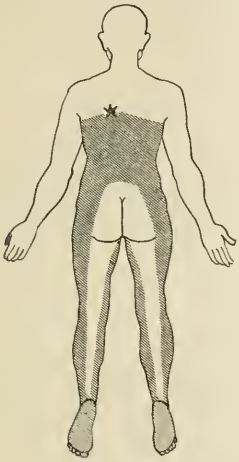

Fig. 1.—The sacral roots are not involved. The * indicates the posterior aching point

of extradural tumor on the contrary, the dura mater is gentrally attacked, and the tumors adhere to its exterior surface, often sending fibers into the interior.

Clinical Study.—The symptomatology of these tumors resembles a good deal the symptomatology of compression of the cord having a slow evolution, but from the clinical as well as prognostic and therapeutic viewpoints, one must distinguish the extra- from the intramedullary tumors, and the present methods of examination render possible a differential diagnosis between these two types.

I. Extramedullary Tumors.—Onset very slow and insidious, occurring in people between the ages of forty and fifty, sometimes in younger people. The first symptom to appear is generally pain which is the result of irritation and compression of the posterior roots. This pain consists of an aching

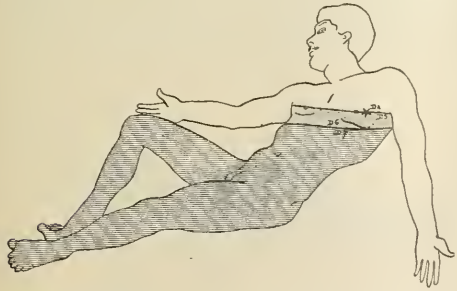

Fig. 2—Progressive paraplegia. Anesthesia of the lower extremities and of the trunk extending up to the level of the 4th or 5th dorsal roots; reflex movements of defense extending to the level of the 6th or 7th dorsal roots. Extramedullary, intradural tumor; operation, cure. The * indicates the anterior aching point.

point or spot of remarkable fixity, situated in the posterolateral part of the thorax, sometimes even in contact with the vertebral column. (Fig. 1.) Very often this posterior aching point is accompanied by a second one situated at the same level but more anteriorly, for instance, in the mammary or in the abdominal region. (Fig. 2.) The pain in these spots is fixed, continuous, and of a neuralgic character, and is generally increased by movements such as deep breathing, coughing, sneezing, or any effort or strain, and being of a neuralgic type, comes in crises and causes at intervals terrible suffering. Strong pressure as a rule does not make it worse, sometimes even calming it, while, on the contrary, any soft rubbing, as the contact of the shirt, is very often insupportable and cutaneous hyperesthesia can be noted at the level of the aching spot. It is very often the only symptom shown during months and years, yet at the end of a certain time, disorders of sensation, slight, but indisputable, can be noted. These consist of painful hypoesthesia, thermic and tactile on a nerve-root zone, corresponding to the painful spot and to the seat of compression. If the tumor is at the level of the upper cervical region, one will find a zone of hypoesthesia, thermic, tactile, and algesic on the external surface of the arm with an aching point on the posterior cervical region. At this period of evolution of the tumor, we are in presence of a nerve-root inflammation. This phase, that we may call *nerve-root phase,* is sometimes very long and sometimes becomes even bilateral, before the medullary symptoms appear.

Fig. 3.—Patient operated upon for an extramedullary intradural tumor involving the 4th to 6th cervical roots.

This occurrence is very rare. Generally with the nerve-root symptom, we note the gradual appearance of muscular atrophy, which also has a nerve-root topography, and taking the preceding case as an example, we will understand the gradual development of the atrophy of the deltoid, biceps, and long supinator muscles (paralysis of the type Duchenne-Erb (Fig. 3.) The exact determination of the aching spot, of the zone of hypoesthesia or anesthesia, and the topography of the muscular atrophy constitute the most important data for a topographical diagnosis of the tumor. The appearance of weakness in the lower limbs and sometimes in all the limbs is the first indication of the cord compression, and marks the beginning of the second phase in the evolution of the tumor. A progressive paraplegia follows. (Figs. 2, 3, and 4.) In the beginning it is always a leg which is paralyzed, the paralysis being more like a paresis. The leg is heavy and above all stiff: in fact, as the diminution of strength appears, the muscular contraction begins and results in a paraplegia. Muscular strength is above all affected in the muscles of the foot, particularly in the extensors. In the thigh the flexors are more affected than the extensors, but there is no marked paralysis. Mobility is compromised by the contracture which causes a spasmodic

gait at least in the case of one leg, which drags on the ground. After a short time paraplegia sets in, both lower limbs becoming involved, but the characteristic of this form of paraplegia is that the paralysis is mild while the mus-

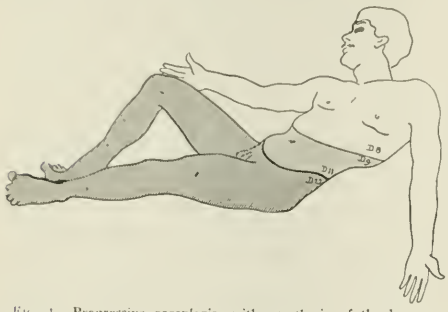

Fig. 4.—Progressive paraplegia, with anesthesia of the lower extremities, extending to the trunk as far as the level of the 8th or 9th dorsal vertebræ. The reflex defense movements exist up to the level only of the 11th and 12th dorsal vertebræ. Extradural sarcoma of the spinal cord.

cular contracture is very marked. Contracture becomes more intense every time the patient tries to make a movement or we try to move a portion or segment of one of the limbs.

Involuntary movements cutaneous reflexes of defense. At times and independently of the will, movements are produced consisting of dorsal flexion of the foot on the leg, flexion of the leg on the thigh, and of the thigh on the pelvis. These movements are almost always accompanied by the extension of the big toe and a certain degree of fan (Babinski). They take place very often while the patient is in bed, and they impress him so much that he complains of it to the physician. They come on spontaneously, or more often follow a very slight cutaneous stimulation. It is this phenomenon that Babinski has named the "cutaneous reflex movement of defense." The movements can be provoked by stimulating the skin in the region situated below the point compression, either by pinching or pricking the skin, or by the application of heat or cold. The cold seems to produce a more active reaction, but these movements are not obtained by stimulation of the skin in the region above the compression and, if they should take place, they would only be voluntary movements responding to an acknowledged sensation. The real reflexes of defense are movements which take place independently of the will and without the perception by the patient of the thermic or tactic stimulation used. It is very important to establish with exactitude the extreme superior limit at which the stimulus brought to the skin can still produce a reflex of defense, the superior line delimiting the zone within which we can provoke the reflex of defense also representing the inferior level of the tumor. It is to be remarked that the reflexes of defense which are so easily provoked on the lower extremities are more difficult to produce the higher we bring the stimulus on the abdomen and thorax. However, there are cases of compression situated high up on the cord in the superior cervical region (pachymeningitis cervicalis pressing the superior cervical roots), in which the reflexes of defense are provoked in bringing the stimulus as high and as far as the inner side of the arm and forearm. (See scheme of Fig. 6.) Of course it is to be remembered that in order to fully appreciate the value of the reflex defense it is necessary to obtain it by stimulating the zone of the skin already rendered anesthetic by the compression.

The tendinous reflexes undergo modifications according to the seat of the compression by the tumor, so they may assume different characters, according to the region of the spine affected. It would take too long to describe separately the conditions of the tendinous reflexes according to the different segments of the spine, but we may say that, as a rule, these reflexes are abolished at the level of the compression itself (if the tumor is in a region of cord enlargement), that we have the inversion of the reflex of the radius when the compression is situated on the fifth or sixth medullary segment, and that the reflexes are generally exaggerated below the compression, with a predominance on the side most affected giving rise to the trepidation rotulæ and clonus, otherwise known as spinal epilepsy. Very seldom we have the Mendel-Bechterew reflex.

The cutaneous reflexes are generally abolished, or at any rate strongly attenuated at the level of the compression and below it. It is to be noted that the difference between the abdominal reflexes may be useful for the topographical and differential diagnosis in the case of tumors of the dorsal region. Babinski's sign is always present at a very early date of development of the tumor.

Sensibility, like motion, is affected at an early date, but the troubles of sensibility will very soon predominate over those of motion. Pains exist from the beginning and consist not only of a fixed aching point but also of irradiation along the whole internal and external surface of the arm, along the thorax (sensation of corset-like constriction), and around the waist (belt-like constriction), and even shooting pains in the lower limbs, according to the seat of compression. As regards anesthesia, I wish to speak of the anesthesia of the lower limbs, spreading higher toward the thorax and affecting sometimes the four limbs. This form of anesthesia of the lower limbs has a peculiar character. At the beginning it is only to be found in one-half of the body, that is to say, on the side less affected in motion (Brown-Séquard). All sensations are affected but especially the superficial sensations.

Superficial sensibility. The different modes of sensibility exist in different degrees. The tactile sensation is almost intact or a slight hypoesthesia is noticeable. The sensation of pain is more affected; the pain most of the time is not felt, or, if felt, zones of paresthesia are present. Thermal

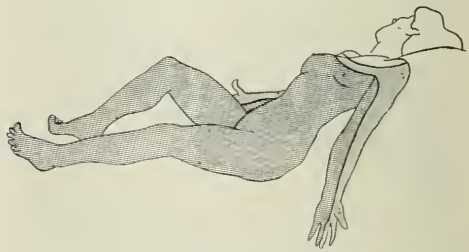

Fig. 5.—Cervical pachymeningitis; heavy shading reflexes of defense; light shading sensation.

sensation is altered: the sensation of heat is generally well preserved or only slight variations are noticeable. The cold is generally not perceptible, or, if so, is felt as heat. The upper limit of anesthesia should be exactly determined. It has the

form of a transverse or oblique line from front to back, and from the lower to the upper part of the thorax and abdomen, and the form of a longitudinal line on the limbs; these lines correspond to the projection on the body of the destroyed medullary areas; we know, in fact, that medullary and nerve root topography enter each other's dominion and are easily confounded. The superior limit of the

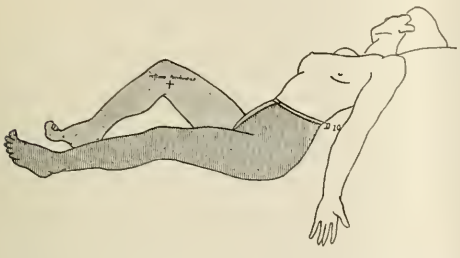

Fig. 6.—Spasmodic paraplegia, especially marked on the right side; anesthesia of the lower extremities and of the trunk as far as the 10th dorsal vertebra, especially marked on the life side (Brown-Séquard). The defense reflexes are very marked in the lower extremities and on the abdomen their upper limit almost exactly coincides with the upper limit of the disturbances of sensation. A case of intramedullary tubercle at the level of the 10th dorsal segment.

anesthesia will then give the location of the upper part of the tumor, while the upper limit of the reflex movements of defense gives the lower limit of the tumor or agent of compression. (See Figs. 1, 2, 3, 4.) Deep sensibility may also be affected with the loss of the sensation of vibrations. This anesthesia and hypoesthesia are not everywhere of the same degree; in fact, Babinski and Tarkoswsky have shown that some regions are less affected and some are absolutely intact. These are the lower sacral areas, especially in tumors highly situated, and are generally the area of S^3, S^4, and S^5 (see Fig. 1). Above the upper limit of the hypoesthesia is found a zone of one or two medullary segments in which sensibility is not intact; they are medullary segments in which the phenomena of edema and compression are still felt. The sphincters are not affected for a long time. The only troubles are symptoms of irritation, difficulty, or slowness in urination, but never incontinence unless the tumor compresses the lumbar enlargement. Constipation is the rule.

Trophic Disorders.—Very seldom edema or cyanosis of the lower extremities occur. Bed sores

Fig. 7.—Different degrees of flexion paraplegia.

are exceptional. The muscular atrophy if existing at the beginning never makes much progress, in fact atrophy only exists at the same level of the compression and has always a nerve root topography. The evolution is very slow but progressive. The

paraplegia is accentuated and the contracture gradually increases until the patient reaches the stage of paraplegia with flexion. (Figs. 7 and 8.) After several months the flexion may become permanent because of the tendinous and periosteal adhesions formed which cannot be broken even under chloroform. At this stage the tendinous reflexes appear to have been apparently abolished but this is only due to the continuous contracture and to the retractions formed. If the limbs cannot be stretched more than two or three centimeters they can at this period still bend and the reflex movements of defense still exist either spontaneously or may be provoked. At this period anesthesia is almost complete. The impairment of the sphincters increases and the patient must be catheterized. If the patient is well taken care of the bed sores will not appear unless great emaciation exists. The general state remains good; there is no rise of temperature, and the pulse is normal. There are patients who remain in bed for fifteen or twenty years and who die only if complications set in, such as bladder infection from catheterism, or pulmonary infection from prolonged decubitus. At this late period all the symptoms of pain have generally completely disappeared.

II. *Intramedullary Tumors.*—Naturally we shall only consider isolated tumors; the multiple ones giving a symptomatology too complex to describe. One may take as a type the tubercle of the cord. Onset: Here also, as in the case of the extramedullary tumors, the onset is slow and insidious and varies according to the seat of the neoplasm. An important point to note is that the nerve root stage so well defined in extramedullary tumors is completely absent in these cases. Pain is rare and if existing is diffused, varying from one moment to the other and not being of that fixed character so important an element in the diagnosis of the extramedullary tumors. Paraplegia is also progressive but of a very rapid evolution, being preceded and accompanied most frequently by a Brown-Séquard syndrome. Mobility is much more affected. Paralysis is real. Contractures also exist unless the tumor is located in the lumbar enlargement of the spine, but these contractures do not, as those produced by the extramedullary tumors, predominate over the paralysis. The stage of complete paraplegia appears very rapidly. Sensibility of every mode is greatly affected at the beginning, being greater on the side opposite to the paralysis at least for the superficial sensibility, but deep sensibility is affected on the

Fig. 8.—Flexion paraplegia complete.

same side as the paralysis (real Brown-Séquard). Afterwards lateral paralysis occurs with its maximum always on the same side. The tendinous reflexes are exaggerated below the compression as in the previous type. The reflexes of defense have

the same character. The impairment of the sphincters appears earlier and is more accentuated. Bed sores as well as the edema and cyanosis of the lower limbs may appear very rapidly; in other words the sensory and motor paralysis have a very rapid evolution and are particularly marked.

Evolution.—After a period of four or five months the paralysis becomes complete. The patient cannot leave his bed and the contracture in flexion ceases. After six months, one year, or eighteen months at the most death occurs, being preceded by severe impairment of the sphincters, deep bed sores, and sometimes even symptoms of flaccid paraplegia if the medulla has been completely interrupted.

Clinical syndrome according to the topography and nature of the tumor: In order to classify clinical syndromes according to the topography and nature of the tumor one must bear in mind the fact that in the case of extramedullary tumors the chief symptoms are the result of the compression exercised by the tumor on the cord, while in case of intramedullary tumors the chief symptoms prevailing are those due to destruction of the morphological and anatomical elements constituting the medulla. These two symptomatologies overlap each other's dominion and the work of the clinician in order to reach a precise diagnosis is a work of discrimination, establishing which of the two manifestations, compression or destruction, is the prevailing in the case examined.

Tumor located in the superior cervical region, 1, 2, and 3 C., between the bulb and the cervical enlargement: Quadriplegia spastic in the upper limbs and flaccid in the lower limbs. The upper limbs are contracted, the arm is close to the thorax, the forearm is flexed on the arm, and the fingers are flexed on the hand. The reflexes exaggerated in the upper limbs. Epileptoid trepidation of the hand occurs. But the two symptoms characteristic of the localization of the tumor in this region are: Bradycardia or slow pulse accompanied sometimes by syncopal and epileptic attacks, and paralysis of the phrenic nerve with its characteristic symptomatology. The muscles involved in an atrophic and sensory way are those of the neck and shoulder. Rotation-flexion extension of the head and painful torticollis also occur.

Inferior Cervical Region 5, 6, 7, and 8 C., and 1 D. (cervical enlargement): Quadriplegia, flaccid in the upper limbs and spastic in the lower limbs. Atrophy of type Duchenne-Erb if 5, 6, and 7 are affected.

Paradoxical reflex of the radius if the 5th and 6th segments are affected. Atrophy of the type Klumpke (thenar and hypothenar eminences) if 8 C. and 1 D. are affected. Myosis, exophthalmus, and narrowing of the palpebral fissure occur. Vasomotor troubles of the face occur on the same side. If the syndrome shows involvement of all the cervical nerve roots we are in the presence of a pachymeningitis.

Dorsal Region: Spastic paraplegia, if there is no total interruption of the medulla. Flaccid paraplegia occurs if the interruption is complete. Troubles of sphincters (retention).

Lumbar Region: (Lumbar enlargement between 10 and 11 D.)

Flaccid paraplegia occurs during the entire course of the disease, with retention of urine—constipation.

Sacral Region 5 L. and 1 and 2 S.: The symptomatology is very complex. The medullary and nerve root symptoms are frequently associated. Paraplegia is always flaccid and is accompanied by muscular atrophy when the degeneration of the anterior roots begins. Deformity occurs according to the predominance of atrophy over paralysis in the case of the different muscular groups.

Inferior Sacral, 3, 4, and 5 S.: No paralysis or atrophy. Special topography of the anesthesia. Impairment of the sphincters and impotence predominate.

Diagnosis.—This varies according to the extra- or intramedullary type.

A. *Extramedullary tumors:* a. Is it a case of compression? The answer is in the affirmative if there are disorders of sensibility, an evolution by nerve roots and medullary stage, and a paralysis which is slight compared to the contracture. b. Is the compression due to a tumor or to a pachymeningitis? This diagnosis is especially difficult in the case of extramedullary tumors which are always spread over a large surface. The pachymeningitis (Fig. 5), either syphilitic or tuberculous, gives nerve-root signs which are very marked and extend over a large area, the process of compression involving sometimes 5, 6, 7, 8, and sometimes more roots. The disorders of sensibility, excepting those existing on the area of the roots compressed, are much less marked excepting in the case of Pott's paraplegia. In such a case the differential diagnosis is determined by the pain in the vertebral area affected; the contracture of the spinal muscles; the evolution which is much more rapid and is generally acompanied by a state of general bad health (an extramedullary tumor lasting for years); the lumbar puncture which generally reveals an abundant lymphocytosis; and the Wassermann reaction which may be positive. Pott's disease isolated without pachymeningitis is exceptional and even in cases of great malformation gives no symptoms of compression.

Vertebral Cancer: This causes painful paraplegia, the very painful paraplegia of old age. Other cancerous localization may guide us in the diagnosis, as sometimes there may be a secondary tumor of the medulla. The evolution is rapid; it may even have a flaccid paraplegia owing to the destruction of a large number of roots. In the case of a tumor pressing on the medulla, the question arises, is it extra- or intradural? In favor of an extradural tumor but always as a symptom of probability, is the large surface covered by the tumor; knowledge is obtained by the situation of the two lines, superior and inferior, the one marking the extremest level where the sensibility begins to be altered, and the other marking the level in which the stimulus brought to the skin can produce a reflex movement of defense. (Fig. 4.) In case of a small and short tumor these two lines will almost be superimposed each upon the other, while in the case of a long tumor the two lines will be separated by a space from ten to fifteen inches long. (Fig. 3, 4, and 6.)

B. *Intramedullary Tumors:* In the case of tumor, the diagnosis is very easily and quickly made, owing to the progressive paraplegia. (a) *A transverse myelitis* has not the same evolution; it appears generally suddenly and if it develops progressively we have always phenomena of a characteristic intermittent claudication of the spine. The movements of defense are generally absent; the troubles of sensibility exist only during the first few days or are entirely absent. We have, besides, symptoms of meningeal irritation demonstrable by the lumbar puncture. One should look for lymphocy-

tosis, albuminuria, and a Wassermann reaction. *Syringomyelia* is easily differentiated on account of its evolution and the dissociation of sensibility. What is the nature of the tumor? In the case of a young subject who has had symptoms of tuberculosis the growth may be a tubercle or one in evolution? In a subject already suffering from a malignant growth it may be a secondary metastatic neoplastic formation of the same nature but localized in the spine. What is the seat of the tumor? The clear knowledge of the clinical syndromes above mentioned, combined with the exact delimitation of the zone of anesthesia above and of the reflex of defense below, and the zone of the medulla involved in the pathological process will always enable one to localize with precision the seat of the tumor. The evolution of the affected zone, joined to the biological examination of the spinal fluid will establish the nature of the tumor or affection.

Reactions of the Spinal Fluid.—The opinions of clinicians on the value of the Wassermann reaction on the spinal fluid have greatly changed in recent years. Their views on the matter have principally been the consequence of the different aspects under which the reaction has been studied, and the results obtained have not always been identical. So, for instance, Nonne of Hamburg stated that in a hundred per cent. of cases of patients having a syphilitic history, the Wassermann reaction of the spinal fluid is always positive. This conception of Nonne taken up by other clinicians ended in creating more radical ideas, making some of them state with earnest conviction that a negative Wassermann reaction of the spinal fluid excludes absolutely syphilitic infection in the patient, but observations of a very recent date made by very prominent observers have brought forward another statement very embarrassing to the neurologists, and that is, that in case of tumors of different nature of the spinal cord and brain, and in case of compression, the examination of the spinal fluid gives almost always a positive Wassermann reaction. This statement, corroborated by true clinical documents, brought naturally some confusion in the interpretation of the Wassermann reaction. Can we explain this fact? Or must we state, as others have already tried, that the Wassermann reaction is not the exponent of syphilis but of conditions of the blood serum that may exist outside of syphilitic infection? To find an explanation, we must take a step back and consider the spinal fluid in its relation to the blood serum.

The spinal fluid, the hydraulic shock absorber and neuro-protector of the brain and spinal cord, is confined to a system of two cavities, viz., the ventricular cavity and the subarachnoid spaces; and is the product of dialysis of the blood and lymphatic serum through serous membranes forming the walls of said cavities, viz., the ependyma forming the ventricular cavity, and the endothelium forming the subarachnoid spaces.

Dialysis is a condition common to all membranes and is a product of several conditions. (a) A constant one which is the attraction that all animal membranes exert on the liquids with which they come in contact. The other factors are variable, that is to say: (1) The pressure and the density of the fluids in contact with the membrane. (2) The permeability of the membranes, due to their special structure and to the changes taking place in their porosity on account of the physiological or pathological conditions arising. Consequently, the process of osmosis may undergo changes for several reasons. Either because of changes in the pressure and density of the fluid in contact with the membranes or because of the changes in their permeability. In the majority of affections of the nervous system we know that the soft meninges, that is to say the serous membrane enveloping the brain and spinal cord, undergo a process of inflammation either acute or chronic. This inflammatory process is proper to the soft meninges and will affect neither the density nor the pressure of the fluids creating the osmotic currents. In which way then will this inflammatory process affect the meninges? Only in one way, and that is by changing their permeability.

My experience with the Wassermann reaction of the spinal fluid and blood serum is, that to a positive Wassermann reaction of the spinal fluid there does not always correspond a positive Wassermann reaction of the blood serum. Also to a positive reaction of the blood serum there does not necessarily correspond a positive reaction of the spinal fluid. These two conditions are then, from a clinical standpoint and from the pathological as well, independent. I do not doubt that every student of the Wassermann reaction has found the same condition. These facts are not contradictory, but only demonstrate that at the base of the Wassermann reaction of the spinal fluid exists a biochemical condition of the meninges which, by itself alone, can explain why the two liquids differentiated only by an osmotic process, should give at times a different toxic reaction in the presence of an identical toxic process. This biochemical condition is the permeability of the meninges which only in special conditions to be determined allows the antibodies contained in the blood to pass into the spinal fluid. This condition is realized by the inflammation of any serous membrane; inflammation which resolves itself into an increased permeability of said membrane. What is true of the peritoneum or of the pleura or pericardium is also true of the meninges; so much so that the old Italian clinician, Cantani, admitted that in certain cases the inflammation of one serous membrane of the body would carry with it the inflammation of all the serous membranes and called the syndrome the Poli-orro-menitis. It is for this reason that many of us in examining patients affected by tumors of the spine specially, have found the positive Wassermann reaction of the spinal fluid, when the reaction of the blood serum was negative and when the history of the patient in what concerns syphilis was, of course, as usual, negative, obscure, or noncommittal. We must admit as an axiom that the patient giving a positive Wassermann reaction has had a syphilitic infection even if he denies it; and if a patient having always given a negative reaction of the spinal fluid suddenly gives a positive one, it demonstrates that in him an inflammatory condition of the meninges is in action, so the only way we can interpret the fact is that the patient affected by spinal tumors or compression of the spinal cord gives a positive Wassermann reaction of the spinal fluid, because either the tumor or the process of compression, by irritating the meninges, has increased their permeability and allowed in such a way the antibodies contained in the blood to pass into the spinal fluid, while the same antibodies would not pass if the meninges were in a normal condition. One may ask, then, why should the blood also not give a positive reaction? Evidently because the antibodies while in the blood find themselves in suspension in a large mass of fluid whereas in the spinal fluid they find themselves in suspen-

sion in a very concentrated quantity of liquid, 60-80 c.c. at the most, and consequently in better condition to show their toxicity when tested for the Wassermann. When we have accepted after five years' experience that the positive Wassermann means syphilitic infection, we cannot create an exception for the reaction of the spinal fluid in spinal tumors. We must then conclude that the positive Wassermann in the spinal fluid, when the other symptom already exists, may be considered as a confirming index of the presence of a tumor or a compression in the spinal cord and will also give the useful information that a remote syphilitic infection is accompanying or is substratum of the pathological condition that we have detected.

Another bit of information that this clinical fact gives and that I consider of great advantage is that a positive Wassermann reaction of the spinal fluid means always, as lymphocytosis does, an inflammatory condition of the meninges, while the positive reaction of the blood serum alone means only a syphilitic infection with a normal condition of the meninges. From the viewpoint of prognosis and therapeutics this information may be considered as a very valuable one.

Massive Coagulation; Xanthochromic Reaction.—Besides the Wassermann reaction, the modifications which may take place in the spinal fluid are of two orders: (a) Those reflecting the inflammation of the meninges itself. (b) Those reflecting the mechanical disturbance produced in spinal fluid by the process of symphysis, a disturbance that the inflamed meninges may create along the spinal cord. The modifications of the spinal fluid created by the process of inflammation of the meninges in itself are purely chemical, and are represented by the changes taking place in the three principal physiological components of the spinal fluid, viz., sugar, chlorides, and albumin. While the modifications of the spinal fluid created by the mechanical and inflammatory disturbances as well, are chemical and clinical, they constitute a very important chapter which must be considered as a corollary to the one of the spinal tumors. This important chapter is given by the syndrome of the massive coagulation and xantochromic reaction of the spinal fluid. In a series of observations of cases of meningomyelitis and of compression of the medulla, it has been observed that the cerebrospinal fluid presents always three special features: (1) It coagulates rapidly in the test tube in which it is gathered at the moment of the extraction. (2) It shows a well marked yellow coloration (xantocromia). (3) It has a diminished tension. All the cases giving this syndrome in which the post mortem was possible, have shown constantly the presence in the spinal cord of meningeal adhesions, and of processes of symphysis between the meninges and the spinal cord; processes which compress the cord and separate the lumbar cul-de-sac from the rest of the subarachnoid spaces, forming in this way two cavities, the inferior a closed one, and the superior communicating with the ventricles. The pathogenesis of the syndrome is the result of the two conditions. (a) A closed cavity separated from the rest of the subarachnoid space in which the different elements of the blood accumulate in the spinal fluid through transudation or hemorrhage. (b) An alteration, toxic or infectious, of the blood vessels of the said cavity, which creates the transudation and multiplies the microscopical hemorrhages in the cavity. This stasis taking place in the closed cavity causes a deficient circulation of the spinal fluid and an excess of resorption which resolves itself in an increase in the albumin and fibrinogen of the spinal fluid. The increased quantity of fibrinogen is the cause of the massive coagulation and the microscopical hemorrhages are the cause of the xanthochromia of the spinal fluid. It is then easy to understand why this syndrome should enter the chapter of the spinal tumors. Its presence may either be the confirming element of diagnosis of a spinal tumor compressing the medulla and creating a meningitic symphysis, or it can be considered as the clinical element excluding the diagnosis of a spinal tumor, when these symptoms are absent, as the majority of cases examined show that this syndrome is characteristic of meningomyelitis and compression of the cord in Pott's disease. And as in the study of clinical facts we must always look for the rules and not for the exceptions, so the presence of the syndrome in affections of the spinal cord may be considered in doubtful cases the discriminating element between a tumor and a meningomyelitis or Pott's disease.

Treatment.—Extra- or intradural tumors. (a) Start always the endovenous specific treatment even if Wassermann is negative and lymphocytosis absent. (b) If no result is obtained, radiotherapy with the penetrating rays may be used. The seances should be one every eight days, sometimes temporary amelioration. If no results are obtained, the course to follow is determined by the localization of the tumors.

A. If it is an extramedullary tumor, surgical intervention should be the treatment. Localize the height of the tumor with precision; localize the vertebræ to be opened, remembering that they do not correspond to the medullary segments. For instance, if a tumor's superior limit is localized at the eighth dorsal segment, it corresponds to the fifth spinal apophysis according to the Déjerine scheme; the surgeon will take this line as the center of the incision and he will open along the line above and below this center, and perform the resection of the vertebral arches. Sometimes after the laminectomy we uncover an extradural tumor. The incision is easy, and the prognosis is good. Sometimes the surgeon may feel the tumor and sometimes he may feel and see nothing. In this case the opening of the dura mater is necessary, but to avoid as much as possible the flowing of the cerebrospinal fluid, the patient is placed in the horizontal position, an incision of the dura mater is performed with a good deal of precaution, and the preliminary opening is a very small one, so that the flow of the cerebrospinal fluid will be slow. The tumor appears posteriorly or laterally, and in this last case the tumor appears covered and interlaced within the posterior roots which are edematous, flattened, and grayish in color. The aspect of the tumor while adherent to the spine is grayish blue or violet. Sometimes it becomes necessary to cut one or two roots before extracting the tumor. The removal of the tumor, which generally is not adherent, but has a ligament near a root, fibrous or vascular, must be done with a good deal of caution and preceded by the ligature of the root. After that there should be very accurate suture of the dura mater with stitches closely approximated to each other and then suture of the muscular masses in several layers.

The prognosis is favorable if the patient survives after forty-eight hours or three days.

B. If the tumor is *intramedullary* the advice of the majority of clinicians is for non-intervention. For a few cases the operation is advised, divided

into two phases: (1) Incision of the dura mater and medulla in the region of the tumor and deep enough to reach the tumor. (2) Second phase, intervention after a few days. The tumor may eliminate itself through the longitudinal incision of the medulla. We have only to gather the tumor or to section the vascular ligament or fibers attaching it to the medulla. The prognosis is very serious, a recurrence being the rule.

Electrical Examination.—The electrical examination of muscles is most important from the viewpoint of postoperative prognosis. If the electrical reactions are normal or simply weakened the prognosis is favorable and we may hope for the *restitutio-ad-integrum* of the mobility in the paralyzed limbs. If the reactions have almost completely disappeared, and especially if the reaction of degeneration is present, the prognosis is very unfavorable. We are in presence of a deep destruction of the trophic centers of the muscles. The paralysis will not disappear after the operation.

Conclusions.—The study of this chapter of neuropathology shows that neurology is asserting itself as a very definite specialty and that it is gradually creating positive methods of physical examination, which will render in the future the diagnosis of the nature and localization of nervous diseases far more precise than the diagnosis of other diseases. The clinician who knows how to find the projection of every square milimeter of the nervous organs on the surface of the body in the form of a motor, sensory, or reflex manifestation, will be compelled to relate cause and effect and localize lesions with a mathematical precision. The conception of Charcot and also the errors of his school are fast disappearing from the field of neurology. But another fact also very important is coming to light, namely, that the real progress in the surgical treatment of nervous diseases is closely connected with a more intimate association of surgeons and neurologists in the determination of diagnosis. The surgeon who feels generally independent from the physician in the performance of his mission and who very seldom asks the physician for his opinion or his views as to the necessity of an intervention must abide by the neurologist when the nervous system is involved. The questions of localization and the opportunities of intervention and technique can be weighed by the neurologist more frequently than by the surgeon. It is only by this closer association that the surgery of the nervous system will be less sad than it has been heretofore.

175 West Seventy-second Street.

CUSTODIAL POWER OVER INMATES OF STATE INSTITUTIONS FOR DEFECTIVES.*

By WILLIAM T. SHANAHAN, M.D.,

SONYEA, N. Y.

MEDICAL SUPERINTENDENT OF THE CRAIG COLONY FOR EPILEPTICS.

It has been well said that all perfection in this life has some imperfection clinging to it for there is no individual without some defect. Those persons who fall decidedly below the normal mental average require, however, to have supervision extended over them by society when their relatives cannot or will not give them the same. In advocating the enactment of a statute to give custodial power over the inmates of our institutions for those plainly defective, I feel that I am but seeking to ensure the best interests of not only the State, but also of these afflicted individuals.

The problem of adequately caring for all persons below the average normal mental state expected of their station in life is one which cannot perhaps be ever entirely satisfactorily solved. Its solution is certainly not as yet within our grasp. Certain measures are available, however, and it is to these to which I wish to allude. The question of prophylaxis as it relates to these defects is still more difficult of application.

During recent years there has been a marked effort toward making an impression on the public as to what mental defect is and what its existence in an individual may result in.

Detailed studies in heredity have shown beyond question that in the majority of mentally defective individuals there is an hereditary defect. Again it has been established that conditions acquired from disease or injury may so affect the brain as to permanently impair the mental state of persons apparently normal at birth. Such injurious factors may begin to act during any period from the time of conception to an adult age, in consequence of which there results a more or less marked mental impairment. In a considerable proportion of defectives there have been present both the hereditary defect and the acquired exciting factor.

In order to attempt to control even in part the occurrence of defectives, active prophylactic measures must be directed against the marriage or cohabiting of known defectives; against syphilis, alcoholism, drug habits, the occurrence of various infectious diseases of infancy and childhood; against the receipt of injuries to the brain at any period of life, etc.

One can at once realize that an absolute blotting out of these causative factors is impossible. Each can be controlled in part, however, and for such reason we should constantly strive to have society as a whole attain the necessary amount of knowledge so as to permit of the active cooperation of all.

I need not dwell at great length on what results from having free in a community individuals who have not the power properly to accommodate themselves to their environment.

Many persons of broad views and extensive experience resemble the newspaper editor who, although admitting that in the interests of charity and for the safety and welfare of society training and amelioration of the condition of the epileptic and feeble-minded should be carried out on a generous and efficient scale, maintains that it is impracticable to consider segregating the socially unfit.

A careful student of the condition must admit that complete segregation cannot be secured nor is it perhaps desired. What those interested are striving for is the legal authority to detain indefinitely in the proper institution such defectives as may be committed thereto and whose relatives or guardians cannot afford them adequate care and supervision outside of the special institution.

A considerable percentage of mentally incompetent persons are those who have been adjudged insane. The remaining portion who are all mentally deficient but not insane in a strict sense include the ordinary feeble-minded, most epileptics, the great majority of whom are also feeble-minded, a considerable proportion of the criminal and delinquent class, all of whom are as much, if not more, of a

*Read before Association of Managers of Charitable Institutions, Albany, N. Y., December 5, 1912.

menace to the public than the mentally unbalanced person who has been committed as insane. The epileptic will be referred to at greater length later in this paper. To reiterate, all persons manifesting symptoms of a departure from the normal mental state, if their relatives are without means to give them proper care, should be committed to special institutions to remain in them as long as their abnormal mental state continues. It should be impressed upon the general public that feeble-minded persons can never become normal mentally. Though physically they may have reached adult years, mentally they remain as children. All must admit that persons who are irresponsible should not be permitted to propagate their kind, either legitimately or illegitimately, if such propagation can be prevented.

I believe it is the bounden duty of the State for its own protection to stop so far as it can the continuance of many of the present conditions regarding the care of the mentally defective classes.

A fact not sufficiently appreciated is that the great class of mental defectives who approach the normal are most dangerous to their fellow men owing to the difficulty in even seeking to control and direct their activities along safe channels. They lack the normal power of meeting in a reasonable manner situations which demand decision.

If I repeat certain matters in presenting my subject, I trust I may be pardoned, as it is done in order to lay more emphasis on phases of the problem under discussion.

Individuals who do not seem able to accommodate themselves in the normal manner to the life of the community in which they live should have their mental state examined by specially trained physicians. If such an examination reveals a mental defect which precludes the possibility of such persons being able to take upon themselves the duties of their particular station in life and it is shown upon investigation that their relatives are unable to give them the proper care and supervision, the State should assume control.

In a recent opinion, the Attorney-General states: "Jurisdiction is inherent in the State over unfortunate persons within its limits who are idiots or have been deprived of the use of their mental faculties. It is its duty to protect the community from the acts of those persons who are not under guidance of reason, and also to protect them, their persons and property, from their own disorder and insane acts."

I will attempt in this paper to give certain reasons, most of which are probably apparent to you, why the institutions for the mentally defective should have a certain amount of authority to detain inmates for an indefinite period. If the various supervisory boards and institutions concerned will but cooperate toward securing legislation which will grant such authority, I am sure that their efforts will eventually be successful.

One must not be too sanguine as to the degree of custodial power which can first be obtained, nor on the other hand, too pessimistic as to the enforcement of a custodial law.

In considering any measure which will deprive an individual of his liberty, due consideration must be given to the rights of such individual as well as to those of the community in which he resides.

One who is at all familiar with existing conditions must agree with me that at the present time there are great numbers of mentally defective persons who are permitted to wander about leading irresponsible lives resulting in much injury to themselves and the community. Many persons are as result of a permanent mental defect incapable of self control, and have opportunities to commit unsocial acts, which, while they may not be serious, entail by their repetition material loss to the community.

An ideal condition would be to have all mentally defective individuals at an early age brought under proper supervision and so kept for the balance of their lives, this being carried out when possible, with the active cooperation of their relatives, so that they would become indirectly wards of the State.

A mentally defective person, as the term is ordinarily understood, is one in whom a defect of strictly speaking does not include persons who have late in life lost their mental powers. The higher grades of defectives may under suitable supervision be capable of partial self support and in some instances practically entirely maintain themselves. The lower grades of mental defect preclude the possibility of such persons supporting themselves even in part.

Adequate control of the feeble-minded as a whole is an ideal toward which we should labor, understanding, however, that an entirely satisfactory solution of such a problem cannot be reached in our day. A step forward would be the enactment of a measure which would permit of the committing to an institution any mentally defective individual upon proper certification of the defective state by competent medical examiners and the commitment to the institution by the proper legal officers. Provision should also be made that where improvement of the defective takes place to such an extent as to permit of his living outside of the institution under proper supervision that such be arranged for.

In striving to obtain legislation toward the end of controlling the mentally defective, we should consider not only what is scientifically desirable, but what can be carried out in a practical manner, taking one step at a time.

A question arises as to how far in a few of the younger patients of the type under consideration we should make a positive diagnosis of mental defect. Change of environment and suitable training in some instances shows that children thought originally to be defective are not so, but are in what has been termed a larval state awaiting proper training and consequent development.

It should be understood by all that, in advocating the segregation of the mentally defective, it is not intended to imprison them, in a true sense of that term, but to place them in a community by themselves where they will receive the care and treatment that their condition demands and be granted as many liberties as are consistent. For the majority of these patients the colony plan would seem to be most satisfactory, remembering, however, that provision must be made for detaining delinquents, who in many instances could not be given the liberty of the open colony system.

There is much controversy as to whether or not the schools in our various cities shall train the mentally defective children during a period of several years. To me the greatest argument against retention of such children in our public schools is that they are not under proper supervision outside of school hours.

It should not be forgotten that perhaps 50 per cent. of the defectives can never be controlled as

they are what are known as borderland cases, approaching in some ways the normal.

It may be that in time many of these borderland cases will enter as voluntary patients into various institutions for defectives, this being brought about by the relatives of such people realizing that they cannot quite accommodate themselves to life in the outside world. Some of these borderland cases might be termed as "feebly gifted," a term used in Europe to describe a certain type who are not called feeble-minded, but individuals who have not had the opportunity of proper training, those referred to above as larval cases awaiting development.

In England at the present time there is being made an active move toward having enacted measures to control mentally defective individuals other than the insane, chronic inebriates, etc. It is the general opinion there, as in many States in America, that the same general law should apply to the insane and the feeble-minded as a whole.

One familiar with the two conditions must appreciate that there is more or less overlapping of the two states so that it is impossible to draw an accurate line of demarcation between many of the later symptoms seen in the insane and those commonly observed in the feeble-minded, the two shading off into one another in the high grade feeble-minded and moron.

Under the existing laws relating to the institutions for feeble-minded and epileptics in New York State, applications to these institutions must be made through the poor law officers, either the superintendent of the poor of the county or the commissioner of charities of the city of which the applicant is a legal resident. The necessity of making application in such a manner may in some instances deter relatives from attempting to have placed in the institution any defective belonging to their family.

As these institutions have been established primarily to care for indigents in preference to patients whose relatives have means, it would seem as though for the present at least such a procedure should be continued, with the arrangement, however, as mentioned elsewhere in this paper, to have experienced medical examiners pass upon each applicant and when he is found mentally incompetent to have him duly committed by the proper court to the special institution indicated. A campaign of education would eventually bring about a state of affairs where many of those defectives belonging to the wealthier class could be admitted for a voluntary period, and thus State control would in time include many who could not otherwise be properly supervised by the State as the result of a measure demanding compulsory detention.

To advocate at this time a complete segregation of all defectives and extensive sterilization of such would in my opinion arouse an antagonism on the part of the public, who would have the natural feeling that such an extensive procedure would mean the committing of a great number of borderland cases who could get along fairly well in the ordinary community. When the public ultimately come to learn, however, that it is only desired to protect such defective persons as are a danger to themselves and others, I am sure that the securing of active cooperation will not be difficult.

Another feature of mental defect which is not sufficiently appreciated is that oftentimes several normal people are deprived of taking an active part in the life of the community as the result of there being in the family one of these mentally defective persons, thus entailing a material loss to society.

Too much stress cannot be laid on the fact that it is a waste of time to provide for mental defectives of a tender age and then lose control of them after they have reached the adult period.

In the organic law governing the Craig Colony for Epileptics, there is a provision as follows: "Epileptic children shall be received into the colony only upon the written request of the persons desiring to send them, stating the name, age, place of nativity, if known, the town, city, or county in which such children respectively reside, and the ability of their respective parents or guardians or others to provide for their support in whole or in part, and if in part only, stating what part; and stating also the degree of relationship or other circumstances of connection between the patients and the persons requesting their admission; which statement in all cases of State patients must be verified by the affidavits of the petitioners and of two disinterested persons, and accompanied by the opinion of a qualified physician, all residents of the same county with the epileptic patient, and acquainted with the facts and circumstances stated, and who must be certified to be credible by the county judge or surrogate of the county; and such judge or surrogate must also certify, in each case, that such State patient in his opinion is an eligible and proper candidate for admission to the colony."

It would seem as if some measure could be enacted so that a method along similar lines to that just described might be carried out for all mentally defective individuals and so drawn as to secure a legal commitment.

The custodial laws enacted within recent years for the Rome State Custodial Asylum, Letchworth Village, and the Craig Colony for Epileptics, provided for the admission of mentally incompetent individuals in accordance with provisions of the laws governing those institutions, but it did not provide for their judicial commitment. An epileptic as such cannot be deprived of his liberty. If he is adjudged insane or mentally incompetent he can undoubtedly be placed under State control.

Our present Attorney-General in referring to the Craig Colony law says: "As the act under discussion makes no provision for trial by jury its constitutionality may be extremely doubtful. However this may be, the act, in my opinion is inoperative as it makes no provision for a judicial determination upon the question of incompetence, provides for no notice to the alleged incompetent and affords him no opportunity to be heard. In my opinion no valid commitment can be made to Craig Colony under Chapter 588 of the Laws of 1911 and the authorities of that institution have no jurisdiction to detain patients against their will or to cause the arrest and return of those who escape therefrom."

A custodial law to be of use should not only provide for the legal commitment of the defective person, but should also provide the authority for the institution to detain all such persons so committed, including the right to arrest and return any who escape from the institution without being properly discharged by the institution or removed by an order from the court. Provision should also be made to prevent the removal of any such incompetent individual unless his relatives could prove that they had the means to give to him the proper care after said relative had been discharged from the institution.

It is a question worth serious consideration as to

whether it would be advisable to have in the custodial law a clause permitting the institution to grant a short parole to certain selected inmates when deemed advisable.

A retroactive law which would bring about the commitment of those now inmates of the institutions for defectives would be very desirable if such a clause could be included in the general custodial law.

From my experience, I am of the opinion that mentally defective persons who have been markedly delinquent should not be placed in ordinary institutions for feeble-minded or epileptics. These persons are difficult to control and require closer supervision than does the ordinary defective. It is possible, however, when the institution has sufficient ground and proper facilities in the way of buildings for classification, so to separate the various types as to permit of the caring for all grades of defectives in any one institution to the capacity of such institution.

Regarding the mentally defective females who are placed in reformatories for women, it would seem as if some authority should be vested in these reformatories to permit of control being had over these defectives for an indefinite period and not for the maximum of three years as under the present law.

It is a well-established fact that the mental condition of a large proportion of epileptics is such that they are as much, if not more, of a danger to the community than the average insane person. The suddent outbursts of irritability, the automatic states following certain seizures, the morbid religious trend, as well as other phenomena preclude the possibility of the majority of them being able to accommodate themselves normally to the environment of the outside world. For their own protection and the protection of the public the great majority of epileptics should, if possible, be at all times under close and careful supervision.

Those epileptics who cannot be given such supervision in their own homes should, it goes without saying, be placed in institutions provided for the special care of individuals of their kind. In other words, the mentally incompetent epileptic should be judicially committed to the special institution to be kept there for an indefinite period. Of fundamental importance in the prevention of defectiveness and degeneracy in the human race is the proper enforcement of strict custodial care of the manifestly defective individuals, this custodial care to be a true segregation and not a mere farcical attempt at the same.

The Craig Colony for Epileptics should at all times have the right to admit as voluntary patients such applicants as are able because of their normal mental state properly to understand the conditions under which they are sent to the institution. Such patients would be permitted to leave the Colony after giving a few days' notice in writing of their intention to do so.

I will cite a few patients recently admitted to Craig Colony as examples of those over whom the State should have the power to segregate for the balance of their days, both for their own good and that of society.

Margaret J., aged 14 years, admitted to Craig Colony November 7, 1912. Father living, age 54; has rheumatism and sore eyes and seems to be nearly blind at times; he is an alcoholic and has fainting spells. Mother died when she was 16 years and 7 months old of diphtheria; she was 15 years and 10 months old when this patient was born and was the third wife of her husband. Maternal grandfather died at 56 of alcoholism; maternal grandmother died at 58 of dropsy and heart trouble. Both maternal grandparents were alcoholics. There is a history of alcoholism and probably syphilis on father's side. A cousin on father's side has epilepsy. An aunt on mother's side was sent to Albion Home Refuge. This patient had spasms when she was 9 months old—at the time she commenced teething. Her epilepsy is said to have commenced at 13 years. She is a right hemiplegic and her paralysis was first noticed at about 10 months of age. She is feeble-minded, rating 7 years by the Binet scale.

Emily M.—Onset of epilepsy at 6 years, admitted to Craig Colony October 1, 1912. Mother died at 41—suicide. This patient passed the Binet test at 8 years. Actual age 20 years. Patient says that after death of mother she was in an orphan asylum in Brooklyn from the time she was 11 years until she was 17 years old. Then she was taken home and became pregnant; was transferred to Randall's Island in March, 1912, and gave birth to a baby July 22, 1912.

Annette W., aged 12 years, admitted to Craig Colony November 15, 1912. Father living, age 37, a waiter by occupation. Mother died at 30 of septic peritonitis (self-induced abortion). Mother had one miscarriage (self-induced). A maternal uncle had epilepsy and died at 12. An aunt was confined in an insane asylum; another aunt has been an imbecile from birth, both on mother's side. The imbecile aunt also had a half sister who was an imbecile. This patient is quite feeble-minded, rating 4 years.

Thomas G., aged 10 years, admitted December 15, 1911. Father living, aged 36 years, painter and iron molder; had lead poisoning a year before marriage. Mother living, aged 36 years. She is neurotic and syphilitic. All of her relatives are said to be neurotic. Maternal grandmother alcoholic, drug habituée, and suicide. Paternal cousin feeble-minded. Maternal grandfather alcoholic and abused family. Onset of convulsions in patient at 9 months. Patient began school at six years, but could not advance beyond first grade. Wassermann test made in November, 1910, positive; after treatment of nearly a year this became negative. Binet test showed mental age six years. Removed by parents December 15, 1911, contrary to advice of physicians.

James E. Mc., aged 24 years, admitted August 2, 1912. Feeble-minded; Binet passed at 10 years. Brother formerly at Matteawan; now in Clinton prison, convicted of burglary. Father was alcoholic. Patient had first seizure at 22 months. He is said to have fallen from a swing at this time.

Walter H., aged 13 years, admitted February 9, 1912. Binet scale eight years. Maternal grandfather died from tuberculosis, as also maternal uncle. Paternal cousin epileptic. Brother epileptic; another had congenital defect of spinal canal as has patient. Onset of convulsions in patient at nine years.

Nathan S., aged 11½ years, admitted June 6, 1912. Binet scale eight years. Maternal uncle epileptic. Mother's family said to be nervous. The mother is a sufferer from sick headaches. Both of the paternal grandparents died from tuberculosis.

Thomas L., aged 36 years, admitted October 15, 1912. Father alcoholic. Patient's younger brother said to have been very nervous and subject to frequent headaches. Maternal grandmother and cousin epileptic. Patient had first seizure at 33 years. He has pulmonary tuberculosis and is syphilitic. He has been alcoholic and has threatened to kill his wife. Mental state is fair with signs of beginning dementia.

We all know that mentally defective individuals vary from the lowest grade, those who are like infants who are unable to protect themselves in any way, to those who differ but little from persons of normal intelligence.

The matter of securing what is practicable in negative or restrictive eugenics must be gradually brought about so far as human means permit and no attempt be made to accomplish at once a general revamping of the human race, as such a move simply arouses an intense opposition and materially retards the effort being made to carry out what seems at present feasible. I agree with the old German maxim which advises: "Make haste slowly."

BILATERAL OPTIC PSEUDONEURITIS AND UNILATERAL MEDULLATED NERVE FIBERS IN CRANIAL INJURY BY BLUNT FORCE.

By MAX TALMEY, M.D.,

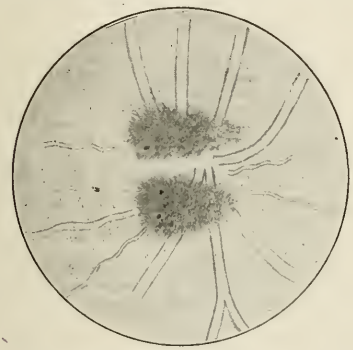
NEW YORK

SURGEON HARLEM EYE AND EAR INFIRMARY.

The case of pseudoneuritis reported by the writer[1] on a former occasion showed how an unfavorable prognosis based upon a mistaken diagnosis became a source of worry to the patient. The case to be described in this article makes clear the importance of the differential diagnosis of optic pseudoneuritis and neuritis from the point of view of treatment. For in this case failure to exclude the former condition before diagnosing the latter made grave remedial measures appear indicated so that a prospect of having to undergo a serious operation was held out to the patient.

On December 4, 1912, Mr. A. A. came to my office to consult me about his eyes. The history of his case, supplemented later by his family physician, is as follows: The patient is 40 years old and has been married for the last 20 years. He has had 7 children. Four are living and healthy, the oldest being 19 years of age. Three died, one was stillborn in the tenth month, one was five days, and one 11 months old. His wife never had a miscarriage. He has always been in good health, hardly ever drinks, and smokes but moderately. He denies infection. His occupation was formerly teaching. For the last 6 years he keeps a lunch room. Except until recently he never had any eye trouble. Six weeks ago as he was walking on an avenue one afternoon at a quarter of five o'clock he was suddenly hit on the back of the head by a stone thrown by a blast in construction work. He fell down and was carried in an unconscious condition into the nearest drug store. He remained unconscious for about three-quarters of an hour. An ambulance surgeon hurriedly called dressed the patient's head temporarily after removing a stone imbedded in a bleeding scalp wound. The patient then, supported by his friends, walked to his home around the corner. He arrived there about an hour and a quarter after the accident and went to bed. The nearest physician was called. He found a deep scalp wound at the back of the head, reaching almost to the bone and about two inches long. He sewed it with one stitch in the middle, leaving the ends open for drainage. There was no fracture of the skull. Soon afterwards the family physician came and found the patient in a fairly good condition. He was rather pale, but in good spirits and talked sensibly, relating exactly everything that had occurred previous to the accident, thus showing that he had no retrograde amnesia. His pulse was regular and accelerated to about 100. The pupils were somewhat narrow, but reacted well. There was no disturbance of sight. Three hours later the family physician called again. The temperature was then 99.5°, the pulse 100. The patient complained of headache and obscurity of vision. His eyelids were frequently twitching, as if light would annoy him. There had been no vomiting. The patient from now on suffered from dizziness and constant violent headache, rendering him unable to sit up in bed. The headache usually started in the occipital region and then became general. The patient would say he felt as if "a hoop encircled his head." or as if "gases arose in his head." As in the erect position headache and dizziness increased, the patient frequently had to be fed with a tube while he was lying. He never vomited. Dizziness and headache of great intensity continued until the middle of the third week. The temperature remained around 100° for about 5 or 6 days and then became normal. The rise in temperature could hardly be attributed to the wound, for it healed by first intention. The pulse which through the whole sickness never showed any irregularity was between 100 and 110 in the first five days, then it gradually decreased in rate and went down to 50. Marked retardation of the pulse was still present in the third week. The reflexes were normal and there were no paralyses or pareses of face and extremities nor any disturbances of speech; the hearing, however, was noticeably impaired for about two weeks.

On the sixth day after the accident a neurologist was called into consultation. After a prolonged neurological and ophthalmoscopic examination with negative result he declared it would take about one more week to determine whether or not the patient had been seriously injured; for the time being he did not think so. At the end of the third week the patient's headache began to diminish in severity, became less constant, and he was able to leave his bed and walk about. Yet for about two more weeks he had to lie down several times a day, being unable to stay up because of recurrent attacks of headache. Not before the sixth week did he feel strong enough nor were the intervals of freedom from headache sufficiently long for him to try to resume his usual occupation. All this time the suffering of the patient was aggravated by visual disturbances. A few hours after the accident he noticed that it was dark before his eyes. The following day things appeared to him smoky as if seen through frosted glass, and he remarked to his family physician that he could not see him distinctly. Yet he recognized everything. He was entirely unable to read, printed or written matter being very blurred. These ocular symptoms grew in intensity as days went by. The pupils were rather narrow but reacted well. At the end of the second week the patient's vision began to get clearer and in the third week he was able to read a little but with difficulty. A blur, bothering him considerably, was usually over the reading matter and he had to hold the latter far away. The left eye annoyed him much more than the right one. In the fourth week yet when he went out of an evening and looked at gas and electric lights, they appeared to him not clearly outlined, indistinct, smoky. In the weeks following the difficulty in reading did not diminish and the haziness



Direct ophthalmoscopic picture of left fundus showing two white areas separated by a strip of red fundus and situated partly on the nerve head partly on the adjoining retina.

of vision persisted to some extent. This ocular trouble added to his occasional, not infrequent, headache, gave the patient a good deal of worry and caused him to seek an ophthalmologist's advice.

Status præsens, December 4, 1912: On the back of the head, directly above the occipital protuberance there is a horizontal scar about two inches long. It is movable, not sensitive, and the bone below and around is smooth, nowhere depressed. The pulse is regular, not retarded, 75 per minute. The knee reflexes are normal. The pupils are of equal medium size. There is a slight simple conjunctivitis. The ophthalmoscopic aspect of the fundi oculorum examined in the direct picture is as follows: The right fundus is somewhat hyperemic, uniformly dark red in color, the caliber of the blood-vessels is rather wide and the veins are not tortuous. The place of the nerve head is recognizable almost through nothing else except the confluens of the blood-vessels, no border of the papilla being discernible. Only temporally, along an arc of the disc of about 45°, a border can be distinguished through a line of pigment adjacent to the papilla, which is a little brighter at this arc than the rest of the fundus. The tissues are nowhere turbid, and there are no hemorrhages on the papilla or retina. The refraction measured ophthalmoscopically in the direct picture is about +2 D. over the papilla and +1 D. over the rest of the fundus. The ophthalmoscopic appearance of the left fundus resembles that of the right one as to color, blood-vessels, and clearness of tissues. The papilla, however, is even less distinct from the rest of the fundus than in the right eye, not even temporally there being the slightest trace of a border discernible. Besides there are two areas glistening white

in color and irregular in circumference over which they appear somewhat striated, each approximately of the size of an optic disc (see figure). These areas are situated nasally, one above the other, and are separated by a strip of red fundus, and one half of each extends into the nerve head, the other half into the adjoining retina, so that the upper and lower nasal quadrants of the papilla are covered, with the exception of the narrow red strip separating the white areas. The refraction is about +2.50—3 D. over the papilla and +1.50—2 D. over the rest of the fundus. As to function the eyeballs move readily in all directions and there is no lagging of one eye behind the other. The reaction of the pupils to light and accommodation is prompt. The fields of vision are normal and no scotomata can be made out. Subjective examination of acuity of vision and refraction gives this result:

VOD=18/20 Hm 0.75 D. V. 18/20.
VOS=20/70 Hm 1.50 D. V. 20/30.*

Diagnosis and treatment. The ophthalmoscopic appearance of the fundi resembled that met with in optic neuritis. There was some hyperemia of the fundi, fullness of the blood-vessels, complete obscurity of the borders of the left papilla and almost complete of the right one, and slight elevation of the optic discs. Yet, considering that the function of the eyes was normal, or nearly so, and that nothing pathognomonic of neuritis, as hemorrhages, was found in the fundi, I made, for the time being, the diagnosis of double pseudoneuritis and medullated nerve fibers in the left fundus. The strong dimness of sight which commenced shortly after the accident and its continuation and the present occasional haziness of vision, could be explained by the cranial injury alone without intervention of neuritis, as will be seen later. The slightly weaker acuity of vision of the left eye was evidently due to its greater error of refraction and the difficulty in reading to the hypermetropia and beginning presbyopia. I applied a ½ per cent. solution of nitrate of silver to the conjunctivæ and prescribed two pairs of glasses, for constant wearing OD: +0.75 D., OS: +1.25 D., and for near work OD: +1.50 D., OS: +2 D. I told the patient that his eye troubles were due to his eyes not being corrected by proper glasses and would cease by using the glasses prescribed, and asked him to return in about ten days.

The patient who all the while had looked rather careworn seemed to cheer up through this prognosis, became more communicative, and related the following experience to explain the cause of his worry. Ten days ago one of his physicians took him to the ophthalmic clinic of a large hospital to have his eyes examined. Drops were instilled into his eyes to dilate the pupils and he was subjected to a protracted examination by several physicians. The chief of the clinic then informed him that his eyes were in a serious condition and that he might have to submit to an operation consisting in opening the skull at the place of the injury where something probably exerted an undue pressure upon the brain. The patient was advised to enter the hospital for observation. From one of the physicians he learned that the diagnosis of his case was inflammation of the optic nerves and "white spots" in the left eye. The information received at the clinic worried the patient very much and he therefore wished to obtain the advice of another eye physician. In order not to influence the new consulting ophthalmologist he did not at first relate his experience at the eye clinic. I told the intelligent patient I did not agree with the serious view held out to him at the clinic, but considered his case to be one of "false inflammation" of the optic nerves, which is a harmless condition. However, a few more examinations at intervals of several weeks would be required to confirm this opinion.

Subsequent examinations. At his second call on December 16, 1912, the patient reported that he was still suffering from headache, mostly at the back of the head. Some days he would be free from it, on other days he would have one or several attacks of headache lasting one-half to one hour and sometimes longer. As to his eyes he felt a good deal better, although occasionally he would still notice a blur in his field of vision. The acuity of vision was again examined and found to be slightly better than at the first examination, in the right eye almost 20/20, with +0.75 D., and in the left eye without correction 18/30 and with +1.50 D. 18/20. Ophthalmoscopically the right fundus appeared a little less hyperemic, otherwise exactly as ten days previously. For a better view of the fundus of the left eye, its pupil was dilated with homatropine and cocaine, which had not been done in either eye at the first examination. Also the left fundus presented the same appearance as before. In the white areas of medullated nerve fibers a few red dots were discovered which at first sight might have been taken for minute hemorrhages. Closer observation, however, showed that those dots were invariably situated over the course of a blood-vessel, proving thereby that they were merely spots where the blood-vessel walls were little or not at all covered by medullated nerve fibers. Although the result of the second examination differed very slightly from that of the first one, I still, for reasons to be shown later, held to the first diagnosis of pseudoneuritis. Desirous of finding out exactly what diagnosis had been made at the ophthalmic clinic I called up on the telephone, December 17, the physician who had taken the patient there and had also examined him ophthalmoscopically. He reported that the diagnosis was double "optic neuritis" with medullated nerve fibers in left eye. The examiners even "thought that they saw hemorrhages" in the fundi. No functional disturbance of note had been found.

The patient did not return for examination before nearly seven weeks. When he called again, February 3, 1913, he reported that he still had attacks of headache of about the same duration and frequency as described at his second call. The headache was now restricted to the lower occipital region and consisted in a feeling of pressure starting in the middle line and extending to both ears. Slight haziness of sight still inconveniences the patient now and then. Besides these symptoms he noticed that he had considerable inclination for sleep, while before the accident he was rather subject to sleeplessness. Ophthalmoscopic and functional examination of the eyes gave the same result as the preceding examination. At his fourth call, on February 26, 1913, the patient reported that he was not yet entirely free from occasional attacks of headache, and added that he was very forgetful. He did not mention anything regarding ocular trouble. Ophthalmoscopic and functional examination of the eyes showed no change of result. When the patient came again, on March 12, 1913, he had little to complain about. For a whole week he had been entirely free from headache, which appeared now at much longer intervals than formerly. No ocular inconvenience was noticed. The ophthalmoscopic appearance of the fundi and the functional power of the eyes were the same as at the preceding examinations. The patient was dismissed and asked to return in about ten months.

Epicrisis. The second examination, made twelve days after the first one corroborated somewhat the diagnosis pseudoneuritis. For the findings, ophthalmoscopically and functionally, were almost the same at both examinations. That the hyperemia of the fundi was a little less and the acuity of vision slightly better at the second examination is evidently to be ascribed to the patient having used for nearly two weeks the glasses correcting his refractive error. The subsequent examinations, seven, ten and twelve weks after the second one, showing no change whatsoever, either ophthalmoscopically or functionally, fully establishes the above diagnosis.

The differential diagnosis of optic neuritis and pseudoneuritis need not be discussed here. The subject has been treated more in detail elsewhere by the writer. Here it may only be mentioned that the essential factor for differentiating the two conditions is an observation extended over a longer period with repeated examinations giving the same results ophthalmoscopically and functionally. This requirement has been fulfilled in our case. The value of this decisive factor is not upset by the presence of another element which would speak for neuritis, namely an etiological factor, as a severe cranial trauma, frequently causative of optic neuritis. That these two apparently conflicting factors may be met with together, as in our case, only adds to the dif-

*This formula means: The eyes have been tested separately. In the right eye vision without correction has been found to be 18/20 (a little less than 20/20) and the refraction manifest hypermetropia (*i.e.* the strongest lens with which best vision is still obtainable) of 0.75 D., correction of which does not improve the vision any further. In the left eye vision without correction has been found to be 20/70 and the refraction manifest hypermetropia of 1.50 D., correction of which improves the vision to 20/30.

ficulty, and emphasizes the necessity of excluding pseudoneuritis before making the diagnosis neuritis. Wilbrandt and Saenger[2] cite a good many cases of cranial injury by blunt force with neuritic changes of the optic papillæ. They consider choked disc consequent upon such trauma as a symptom of increase of pressure in the dural space and, in the majority of cases, intracranial bleeding as the underlying cause of this increased pressure (l. c., p. 789). In many of those cases the choked disc passed away spontaneously. In one of them neuritis and loss or impairment of vision disappeared promptly after a cranial operation by which fragments of bone and intradural blood clots were removed from the skull (l. c., p. 788). Now, if in our case there were true optic neuritis, this condition and the persistent violent headache would have justified the assumption of undue intracranial pressure caused by the powerful cranial injury and perhaps offered an indication for a cranial operation to remove the basis of this increased pressure. But if we have only a negative ophthalmoscopic result, *i. e.* pseudoneuritis, in our case, then it is to be classed with another group of cases cited by Wilbrandt and Saenger, in which the result of ophthalmoscopic examination was negative, the visual disturbances gradually disappeared, and *restitutio ad integrum* followed (l. c., pp. 742, 745, 747).

For proper interpretation of our case from a neurological and especially from an ophthalmological point of view early observation in this respect immediately, and within a few days, after the injury would have been required, but is unfortunately lacking. The neurological symptoms as reported by the intelligent patient and the family physician consisted in unconsciousness directly after the injury and later in dizziness and constant violent diffuse headache for nearly three weeks, and marked retardation of the pulse rate beginning at the end of the first week and continuing for about two weeks. This symptom complex would correspond to concussion of the brain, as elaborated by Trendelenburg and Windscheid.[3] Ophthalmoscopically it would have been valuable to have determined whether shortly after the injury the patient had an amaurosis of brief duration followed by visual disturbances of hemianopic character. The patient did not know of any such symptoms. Ascertaining such visual disturbances would have helped to corroborate the diagnosis of concussion of the brain with special participation of the occipital cortex. For, in order that visual symptoms after a cranial injury may be utilized for diagnosing concussion of the brain, it is requisite, as Camil Hirsch[4] has pointed out in a very instructive case of cortical blindness through commotio cerebri without ophthalmoscopic findings, that their onset follow the trauma directly, that they have the highest intensity right from the start and then gradually diminish and disappear in a comparatively short time. This requirement is not fulfilled in our case. Judging from the report of the family physician and the patient, visual disturbances commenced a few hours after the trauma, grew in intensity the days following, and began to diminish at the end of the second week. Assuming that they consisted in hemianopic amblyopia and were therefore due to some insult to the visual tracts or to the centers in the occipital cortex, the most plausible anatomical explanation would be an intracranial bleeding produced by the trauma. While in concussion of the brain visual symptoms are fully developed at the moment of the injury and are rather transient, in pressure on the brain through a hematoma some time is needed for development to greatest effect of the symptoms and more time yet for them to recede through absorption of the blood. It appears that in our case this was the mode of their development and retrogression. While therefore the neurological symptoms in our case may be explained by concussion of the brain, the visual disturbances would not speak for such a lesion, but rather for intracranial hematoma. Of course it is possible that both these conditions were present, the neurological symptoms being due to their combination, or to one of them, and the ocular symptoms to the hematoma. Retrograde amnesia which is a prominent symptom in concussion of the brain was lacking in our case according to the positive assertion of the family physician who had examined the patient in this respect about two hours after the injury.

These few remarks may suffice for the neurological aspect of our case. The latter was not in the scope of this article, which is merely intended to illustrate the importance of recognizing optic pseudoneuritis, especially in a case in which neuritis would indicate recourse to grave remedial measures. Wilbrandt and Saenger (l. c., p. 618) mention that pseudoneuritis should be borne in mind in a group of symptoms pointing to tumor of the brain. Although they do not add a similar remark in the discussion of cranial trauma, this warning holds good here no less, as clearly shown by our case.

HEXAMETHYLENAMINE IN SURGERY.*

By A. C. BURNHAM, M.D.,
NEW YORK.

In 1889, Nicolaier[1] demonstrated the presence of hexamethylenamine in the urine of patients to whom it had been given by mouth. He found free formaldehyde in these urines, and consequently advised the use of hexamethylenamine in the treatment of infections of the genitourinary tract. Six years later, in 1895, he published a second report with the result that the drug soon received general recognition, and was widely used. It was not until 1908, when Crowe[2] pointed out the secretion of hexamethylenamine in cerebrospinal fluid and in the bile, that the profession began to regard it as a drug possessing a

*In this article hexamethylenamine has been considered solely from the viewpoint of the surgeon. Its large field of use in internal medicine has only been touched upon.

much broader field of usefulness, and to study its effect in conditions widely separated from the previously limited field of genitourinary conditions. I have attempted in this article to correlate much of the experimental work that has been done and to point out its peculiar application in the field of surgery.

The testimony in favor of hexamethylenamine has been both clinical and experimental, the experimental fulfilling the requirements of scientific exactness generally lacking in clinical reports. Hexamethylenamine has been placed on the market by various manufacturers, under a variety of names, urotropin being probably the best known. This list has been further extended during the last few years by many combinations which owe their activity to hexamethylenamine and which do not differ essentially from the drug itself. Hexamethylenamine methylene-citrate has been advised as acting in alkaline as well as acid mediums, and other similar combinations are now under trial. Whether they will fulfill the promises made for them or not is a matter which only time can determine.

Hexamethylenamine is one of the best examples of a product of true chemico-therapeutics. It is a synthetic product and acts as a poison on the infecting organism much in the same manner as quinine and salvarsan act in malaria and syphilis; that it, is injures the infecting organisms more than it does the body tissues. When hexamethylenamine is given either by mouth or rectum, or by hyperdermic injection, it appears, after a short interval, usually less than an hour, in the urine and in various other secretions, giving to the secretions in every case an antiseptic property. Hexamethylenamine, itself, has only a very slight antiseptic action, but when added to acid urine formaldehyde is liberated by virtue of which the urine becomes antiseptic. On this point practically all investigators were agreed, but as the drug was used more generally and good results were reported in cystitis with neutral and alkaline urines, it became necessary to inquire further into its action under such conditions.

Sollman,[3] in 1908, was able to prove that the urine when passed did not contain demonstrable quantities of formaldehyde, and that this substance was liberated only after one and one-half to two hours; and many observers have reported the absence of free formaldehyde in the urine, bile, and other fluids after the subject has been given hexamethylenamine in therapeutic doses. Churchman,[4] in 1906, found that the urine of patients taking hexamethylenamine had an inhibitive effect on bacterial growth outside of the human body, and Crowe was able to prove this action in the bile and cerebrospinal fluid. We have here then a drug which breaks down in acid urine, and which in watery solutions is only slightly antiseptic, acting as an active antiseptic in neutral and alkaline body fluids. How then does it act?

There are two groups of observers, the first saying: "The drug acts only by virtue of the liberation of formaldehyde; it can consequently have no action in cerebrospinal fluid and alkaline urine, for we have tested the fluid and the urine, and although there is hexamethylenamine present there is no free formaldhyde." The second group answer: "We have tested the cerebrospinal fluid and the alkaline urine, and when hexamethylenamine is present there is a distinct retardation of bacterial growth." The answer to these apparently conflicting statements is absurdly simple. The first group is wrong. Hexamethylenamine can and does break down in alkaline solutions, especially when there is stasis of the solutions, and when they are kept at body temperature. This takes place both in the body and in vitro. These points have been very clearly proven by the experiments of Ibrahim[5] and of Zak,[6] who have shown that when hexamethylenamine is mixed with cerebrospinal fluid and allowed to stand for twenty-four hours in the incubator at 37° C., there was a slow but constant liberation of formaldehyde. Zak tested the disinfecting power of hexamethylenamine at different temperatures and found that a 0.5 per cent solution at 37° C. was as strong as a 2.0 per cent. solution at 17° C. We are therefore justified in the assertion that hexamethylenamine has an antiseptic action in alkaline and neutral body fluids when kept at body temperatures, and that this action is greater in those cases in which stasis allows time for the liberation of formaldehyde to take place. Granted then, that this drug exerts an antiseptic action in neutral and alkaline fluids when kept at body temperatures, in what types of cases will its use be of advantage to the surgeon? It should be remembered that hexamethylenamine has two great fields of action; first, as a prophylactic against infection; and secondly, as a curative agent after infection has already taken place. Its value as a preventative of infections is an important one, but it is difficult to prove and is too often overlooked.

Hexamethylenamine has been most frequently prescribed in infective conditions of the genitourinary tract. Its value here is well recognized, and it is prescribed in cystitis, pyelitis, and other conditions due to bacterial infection. Ibrahim has shown that the disinfecting power of hexamethylenamine varies for different organisms, and it is possible that, in some cases where the results have been unsatisfactory after its use, an organism especially resistant to the action of formaldehyde has been the etiological factor. In acute conditions hexamethylenamine should be given in doses of from 20 to 40 grains daily. It is said to increase the acidity of the urine, but this has never been clearly demonstrated. In chronic cystitis, especially when due to an enlarged prostate, it is of great value. In such cases I have seen the drug given over a period of several years without ill effects. In tuberculosis of the bladder I have never seen it used and would not expect any results except in cases where there is mixed infection. It should be more frequently used as a prophylactic. Before every catheterization; before all instrumentation; before every operation and after every wound of any part of the genitourinary tract it should be used in full doses. The following routine has been advised for cystoscopy: 10 grains are given from four to six hours before the cystoscopy and 7½ grains are given one hour before beginning the instrumentation. For the next forty-eight hours 7½ grains are given every four hours.

When first introduced hexamethylenamine was advised in the treatment of renal and vesical calculi. There are no experimental data to show that it has the slightest value in the treatment of calculi by virtue of any power to cause the solution and disappearance of the calculus, but in many cases it may be of great value in the prevention and cure of the infection which so often accompanies stone.

Crowe, in 1908, reported the presence of hexamethylenamine in the human cerebrospinal fluid, and by a series of experiments on dogs he showed very conclusively its value in the purulent types of meningitis. The following is from an article written by

him in 1912:[7] "Following a subdural inoculation of dogs and rabbits with a virulent culture of streptococcus, sixty to eighty grains of hexamethylenamine a day, given under conditions which insure absorption, will markedly defer, and in some cases prevent the onset of a fatal meningitis. This conclusion is based on the results of forty experimental observations. In each experiment four animals were used. The dura in each animal was exposed, under aseptic precautions, by a trephine opening in the broad posterior arch of the atlas, and 0.1 c.c. of a bouillon culture of streptococcus was injected into the cerebrospinal space. One animal in each experiment was used as a control; the other three receiving hexamethylenamine under varying conditions and in varying amounts. In no case did the control animal survive longer than thirty-six hours, and on examination a diffuse, purulent meningitis was found; in many of the others the progress of the infection was held in abeyance during the continuance of active therapy, but as soon as the drug was withdrawn the organisms immediately began to multiply, with a return of the clinical symptoms. A few of the animals, however, made a complete recovery. . . . It is worthy of note that the only animals which recovered after a direct subdural inoculation were those to whom large doses of hexamethylenamine were given, as a *prophylactic* measure, for several days preceding the inoculation." The work of Crowe has been substantiated by the careful experiments of Hald,[8] who found hexamethylenamine in the cerebrospinal fluid in some cases as high as 1-25000. Similar results were obtained by Ibrahim, Weinrich, and many others. Hexamethylenamine should therefore be used in all cases of compound fracture of the skull; before all operations in which the dura is exposed, and in every condition where there is danger of a complicating meningitis; such as cellulitis of the scalp, mastoiditis, etc. Crowe reports thirty-five cases of compound fracture of the skull, in which hexamethylenamine was given as routine, without a single case of complicating meningitis.

In developed cases of meningitis its value is less marked. Brem and Zeiler[9] reported two cases of influenza meningitis which apparently improved under the use of hexamethylenamine, but which finally ended fatally. Crowe gives a very interesting report of a case of streptococcus meningitis in a child seven and one-half years old treated with enormous doses of the drug and ending in recovery. This child was given 939 grains during twenty-two days, an average of 42½ grains a day, and during the first forty-eight hours this child, seven and one-half years of age, received almost 300 grains. If one child, with a daily temperature of 105 and spinal culture positive for streptococci recovers under the exhibition of any drug, a further trial of the remedy is indicated. Two cases of streptococcus meningitis following compound fracture of the base were treated by the writer in 1908. Both of these cases ended fatally, but in view of Crowe's report, the daily dose of 100 to 140 grains which they received was entirely inadequate.

Closely related to the action of the hexamethylenamine in the cerebrospinal fluid, is its action in the ear. In 1910 Barton[10] reported the finding of the drug in the fluid discharge from the middle ear, and it has been used in the prevention and treatment of otitis media and mastoiditis. It has also been advised in infective rhinitis (Eisenberg,[11] Miller[12]) and has been found in the aqueous humor of the anterior chamber (Gradle[13]). These findings would suggest its use by the specialists in operations in these regions. Crowe's first experiments called attention to the presence of hexamethylenamine in the bile, and since then he has used it repeatedly in order to prevent and cure the chronic typhoid infections of the gall bladder. Its use in acute cholecystitis and the chronic inflammation due to gall stones is often followed by very striking results (Chauffard[14]). It should be used as a routine prophylactic before all operations on the gall bladder or ducts. Its value in infective cholangitis is problematical, but theoretically it should be of value. Zak found that, clinically, in a case of gastric fermentation due to stasis, hexamethylenamine prevented the fermentative changes. The patient was given full doses for four days and the vomitus which had previously been very foul became odorless and the patient felt much more comfortable. This action might be taken advantage of when operation is contemplated upon a stomach in which putrefactive changes are taking place.

Hexamethylenamine has been demonstrated in the sputum (Armstrong and Goodman[15]), in the blister of zoster (Zak), in the blood (Hald), in the saliva (Hauzlik[16]), and in other secretions. When present in these secretions it is usually found in sufficient concentration to inhibit the growth of bacteria. I do not find any record of its presence in the fluid of pleurisy with effusion, in the synovial fluid, or in the peritoneal fluid, although it is reasonable to suppose that it would be found in these fluids at least as strong as it is found in the blood, and in such concentrations it would be of distinct value as a weapon against infection. Should this be true we have in this drug an agent against infection which acts over a wide field and which is destined to come into almost universal use in most types of surgical inflammation.

The dosage varies with the object in view. In the bladder, small doses of from 20 to 40 grains daily are usually sufficient while in infection of the gall bladder and of the meninges extremely large doses must be given. Often from 200 to 300 grains a day are given in severe cases. I have found that when action on the meninges is desired, much larger doses may be given if the drug is combined with enough alkali to render the urine neutral or alkaline in reaction. In this manner I have frequently given 15 grains every two hours for many days without any bladder irritation, or any change in the character of the urine.

Hexamethylenamine should always be given well diluted, about one ounce of fluid being given with every two grains of the drug. As it is almost tasteless it may be added in this proportion to the fluids given. Apparently a very few patients have an idiosyncrasy to hexamethylenamine, and in such patients a small dose may cause hematuria associated with painful and frequent urination. Many such cases have been reported, but it is the general experience that they invariably clear up under the exhibition of fluids and alkalies in large amounts. Rovasic[17] gave rabbits large doses of helmitol, a hexamethylenamine compound, over a period of fifty-three days; at the end of that time there was no pathological change in the kidneys. Frothingham[18] has reported congestion and hemorrhages of the gastric mucous membrane after the subcutaneous injection of hexamethylenamine in guinea pigs, and gastric irritation and vomiting has often occurred, after the giving of large doses, in human

beings. It is apparent then that the chief points of irritation are the stomach and the bladder. In both of these places the normal reaction in acid and formaldehyde is freely liberated. If such an action takes place these are exactly the two regions where it can be most easily controlled by the action of alkalies.

The mode of administration is usually by mouth, but should the occasion demand it, it may be given either by rectum or subcutaneously. The last method has been advised by Gundrum,[19] who says: "The ordinary tablets were merely boiled in water and injected rather deeply into the thigh." He says that thirty grains at a dose may be given in this manner with only a very slight reaction. In the same manner the drug has been given by intraspinal injections in the course of the treatment of meningitis.

In conclusion I wish again to call attention to three cardinal points in the use of this important therapeutic remedy, and to urge that unfavorable reports regarding ineffectiveness and toxicity be discounted unless these three points receive careful consideration. The points to be remembered are as follows: Hexamethylenamine must be given early; it must be given in sufficient doses; and it must always be given in sufficient dilution.

SEXUAL PERIODICITY IN THE MALE.*

By C. P. OBERNDORF, M.D.,

NEW YORK.

For more than a century isolated observations have led investigators to believe that men, as well as women, present various signs of a physiological menstrual cycle. While Havelock Ellis[1] has with infinite pains compiled the numerous examples recorded in the literature up to 1910 when his latest edition of "Studies in the Psychology of Sex" appeared, the evidence of a phenomenon in males corresponding to a menstrual period cannot be considered as altogether conclusive.

Among many other cases recorded by Krafft-Ebing, Naecke, Moll, and others, Ellis quotes two instances which are in many respects the counterparts of the first two cases to be reported. The first, observed by Clouston in 1882, consisted of a "regularly occurring brain exaltation every four weeks, at times progressing to maniacal attacks, with a concomitant increase in the nisus generativus" and the second, described by Feré in 1905, manifested "a tenderness and swelling below the nipple every twenty-five to twenty-eight days accompanied by sexual excitation and erotic dreams."

Certain carefully kept records on the part of normal individuals of their sexual desires and nocturnal emissions have shown significant indications not only of a monthly but also of an annual sexual cycle. Ellis, however, further remarks that "It is in the domain of disease that the most strenuous and on the whole the most successful efforts have been made to discover a menstrual cycle in man. Such a field seems promising, for morbid exaggerations or defects of the nervous system might be expected to free from inhibition or to emphasize fundamental rhythmical processes of the organism, which in health and under the varying conditions of social existence are overlaid by the higher mental activities and the pressure of external stimuli."

Case I.—The first case, which resembles Clouston's, is that of an Englishman, violinist, single, age 29, who was admitted voluntarily to the Manhattan State Hospital, Wards Island, in June, 1912, just after one of his monthly depressions. He is one of thirteen children, but the only one apparently who shows distinct abnormality. He believes that he resembles his father in character, for the latter was erratic, hot tempered, and inclined to take long trips. He adds that it was well known at home, that about once a month "my father would become violent, irritable, and passionate, and at such times had to be handled by the family with care." His mother, who is still alive, is apparently normal. The maternal grandmother died of a senile psychosis and the maternal grandfather was of a psychopathic constitution.

From babyhood the patient developed feebly as he was afflicted with fragilitas ossium, through which he sustained 16 to 20 fractures of various long bones before the age of 22 years, though since then he has been immune. Otherwise his general physical health has always been fair.

Shortly after the age of six the patient manifested a desire to wander away from home into the fields, and it was not long before his mother began to notice that these wandering expeditions would occur once a month at about the time of full moon. Although the patient's sexual awakening occurred at five or six with infantile fancies about female members of the household and active masturbation began at the age of ten, periodicity in his sexual excitement, coincident with lunar changes, was not observed until he reached puberty. As a boy of thirteen he experienced nosebleed during one of his excited periods, but there has been no periodical epistaxis.

While he has observed that though once a month, at the time of full moon his erotic cravings are strong, it is curious that unless he is in his period, his sexual desires are very mild indeed. His citation of many examples of relative absence at one time of his desires and extreme augmentation at others with the same or different women (the patient has lived in common-law relations with a woman in London for two years) substantiates his assertion. Because he appreciates that during these periods his sexual cravings are almost uncontrollable, he has made it a practice for some years to avoid women at such times for fear that he will commit some serious indiscretion. At the time of the period he usually also feels a marked increase in energy, physical power, and ability to play on his violin, but at others experiences restlessness, depression, and anxiety. During one of his periods at the age of sixteen he was so excited as to require commitment to the Leeds (England) Insane Hospital. Judging from a retrospective account this appears to have been a maniacal attack.

Since puberty he has never known the periods to fail, excepting on two occasions, when as ship's musician he took trips to South Africa and Australia. Though he recalls that on both these trips the moon was shining brightly, he noticed no change in his emotions. As there is only a slight difference in the time of month for full moon in the Antipodes and northern latitudes, it is possible that the absence of the periods may be explained by the same curious phenomenon which causes a cessation of menstruation in women when they go to a climate to which they are not accustomed.

The purely psychical effect of moonlight and erotic

*Presented before the New York Neurological Society, November, 1912.

fancies connected with it, to which the excitement might perhaps be attributed may be excluded by the regular occurrence of the periods at monthly intervals when the moon was obscured or when the patient was placed in such situations that he was unable to see it, as during his long confinement to various hospitals while convalescing from his numerous fractures.

During his residence in the Manhattan State Hospital the patient awoke on July 10 after an emission. On the following three days he passed through a state of restlessness, mild depression, and irritability, which he describes as follows: "I have been melancholy for the last three days. At 5 A. M. Sunday I awoke after a nocturnal loss and have had no desire since. I miss my violin and my work, and most of all I miss the society of my dear lady friend. I think that the loss of her good counsel is the cause of my melancholy. This state will pass, as it always does, and I am becoming indifferent. My thoughts during this period are not worth putting down on paper. They only embrace the usual imaginations of a love-sick fool. Love is only miserable lust, and if I can overcome these periods I shall be happy without female society. There is nothing more I can say. My appetite is not impaired. Nothing but a strong desire for the old environment of the bright footlights."

As he was deported to England, no further periods were actually observed, but when last heard from he was again working as a musician on shipboard.

The above case is primarily an example of periodicity in connection with a psychopathic make-up. However, it is also to be expected that the existence of periodic sexual rhythms would be particularly manifest in persons showing secondary physical sex characteristics of the opposite sex. Such characters may grade from mere tendencies to effeminacy in facial expression or voice, to actual anomalies. Theoretically it is possible that extreme incongruity between external sexual and internal generative secretions may exist, and such a complete antithesis has recently been described by Magnus Hirschfeld.[2] It concerned a young person of twenty who had been educated as a girl but who evidenced unmistakable masculine social tendencies from early childhood. Examination revealed a perfectly developed female so far as breasts and genitals were concerned but the "young woman," who had experienced orgasms since the age of eighteen, had ejaculations of spermatozoa from an otherwise normal female urethra. Eventually she was legally declared to be a male and married a female companion.

The next patient to be described cannot be considered such a hermaphdrodite, but rather a male individual showing particularly the presence of a well developed breast and monthly sexual cycles. His mental states shows a reaction reminiscent of Adler's theory[3] that many psychic disorders have their basis in an inferiority of the sexual organs and that psychoneuroses are the result of a masculine protest against such a weakness.

Case II.—The patient, a machinist, who came to Dr. C. L. Dana's service of the Cornell University Medical School Dispensary complaining of nervousness, was born in Illinois in 1883 and gives a negative family history with the exception of epilepsy in one brother. No abnormality similar to his own exists, so far as he knows, in any other member of the family. His general physical health, aside from the malady under consideration, has always been good. No venereal infection or excessive alcoholic indulgence.

His physical development progressed normally until the age of thirteen when he noticed that the left breast began gradually to enlarge. Two years later it had attained its present development—a soft, slightly pendulous breast, about the size of that of a girl just passed puberty. The musculature of his body is firm and distinctly outlined, the body quite hairy, the external genitals fully developed, and the pubic hair of the male type. The skeletal formation is masculine on the whole, though the hips are a trifle large and there is a marked tendency to narrowness at the waist and also to lumbar lordosis.

The patient's face is strikingly youthful, so that he might readily be taken for a youth of twenty instead of a man of twenty-eight. The hair of the face is fine and so sparse that it is necessary for him to shave only once or twice a week. Although the voice "changed" at seventeen, it still remains decidedly soft, drawling, and rather high pitched.

From the age of 15 to 18 the patient indulged in masturbation about three times a week, but then abandoned this practice for normal sexual intercourse. It was then that he became aware that his sexual desires were active only once a month, usually about the twenty-second, at which time they became extremely strong. At the same time of the month he would also notice that the left breast would become firmer and more erect, and would also be subjectively sensitive and tender for about four days. For the past two years an oily secretion has appeared about the nipple at such times.

Seven years ago while rubbing the left breast with a coarse towel after bathing he observed that the friction caused an erection of the penis. The same reaction occurred subsequently when a physician whom he consulted for his neurasthenic symptoms, in administering electricity, happened to place an electrode over the left breast, and subsequently manipulation of the breast has produced erections.

Although the patient is more or less continuously in an uneasy and bashful state, the mental symptoms are more marked at the time of his periods. He becomes restless, easily frightened, irritable, and is subject to an annoying vertigo and flushes of blood to the head. For the past two years he has avoided sexual intercourse because of waning sexual desires, but at the time of his periods he is troubled by frequent involuntary nocturnal emissions. While actual failure in coitus has never occurred, his pollutions have led him to fear impotency. Homosexual traits or even masks of homosexuality, which often accompany such secondary sex traits, have not been revealed.

Because of the remarks, chaffing, and annoyances to which he has been subjected at the hands of his acquaintances and fellow workmen on account of the breast, which is sufficiently enlarged to be noticed through his working shirt, he has gradually withdrawn from society and become more and more seclusive. He has abandoned athletics in which he was formerly very interested, because of the necessity of undressing before men, and he is even loath to continue his trade of machinist because of the vexations to which he is exposed.

The patient has been treated with orchitic substance with meager result. It would not be surprising to see him eventually drift into a dementia præcox state unless he can be brought to consider his affliction more lightly.

Case III.—The following case, referred to me by Dr. Leo Buerger, presents a complicated picture from a psychical standpoint and is only briefly reported for the symptom of periodicity in connection with mild physical signs. He is an American of colonial ancestry, single, aged 29, a clerk, whose chief complaints on first consultation were depression, irritability, and lack of concentration.

Heredity negative with the exception of "nervousness" in the mother, who is still living at an old age. No diseases of childhood. Pneumonia at 26. Drinks and smokes in moderation.

The patient is thin, pale, of frail skeletal build. He is small, slender, waist narrow, and hips proportionately large. Very marked hairy growth over chest, legs, arms, and back. Genitals normally formed, though not well developed. The voice, gait, and many mannerisms are distinctly feminine.

Patient began masturbation at the age of five and has continued it practically up to the present time. At first, masturbation was practised alone, but later he became passive agent in pederasty with his two brothers, who were respectively fourteen and eight years older than the patient. Sexual relations with his brothers ceased after a bitter fist fight with his younger brother at the age of fifteen. Heterosexual intercourse only on three occasions at the age of twelve with a girl of the same age.

Since the age of fifteen the patient has abstained from any form of physical sexual relations with persons of either sex. His psychical homosexual component is very pronounced, as there are at least five instances of marked attraction toward men of the definite masculine type. He has roomed with most of these men, and while, as before stated, he has never had relations with them, he made many sacrifices to retain their friendship, such as cooking, washing, and keeping house for them and lending them money. With women he has always been more of a

companion than a suitor, a receiver of intimate confidences, and a friend whom they met on a basis of equality. In his tastes he is an esthete, with strong likings for the artistic in music and painting and an aversion for the gross and vulgar.

Periodicity.—When he returned to masturbation after the quarrel with his brother at fifteen, the patient gratified himself too frequently to observe any periodicity in his desires. At nineteen, however, when he began to attempt to suppress his habit, he noticed a regular variation in the intensity of his desires, therein that at the time of full moon no amount of effort succeeded in controlling them.

This lunar increment in his sexual cravings has continued without fail up to the present time. He believes that the psychical effect of moonlight is a negligible influence in his case, for, as he points out, the moon remains bright for several days after full moon, but his sexual longings disappear completely after reaching a climax at or about full moon, only to recur after another twenty-eight days. Moreover, the same excitability exists at lunar periods when the moon is not visible. Of recent years, since the patient has almost conquered his masturbation, nocturnal pollutions occur regularly at such times.

FOREIGN BODY IN RIGHT BRONCHUS. LOWER BRONCHOSCOPY. SUCCESSFUL EXTRACTION.*

By GERHARD HUTCHISON COCKS, M.D.,

NEW YORK.

JUNIOR SURGEON, MANHATTAN EYE, EAR AND THROAT HOSPITAL.

A boy two years old, of Italian parentage, living in Mount Vernon, N. Y., was brought to Dr. Chappell's clinic at the Manhattan Eye, Ear and Throat Hospital on February 3, 1913. From the mother, who spoke but little English, it was learned that the child had been sick with a cough and labored breathing for the past twenty-four hours. The boy had been crying, and was given peanut candy to quiet him. He coughed violently after receiving the candy, and it was feared that some of the candy might have entered the larynx.

The patient was a well nourished child, temperature 101 deg. F., respirations 28, pulse 128. Examination of the chest was negative. The respirations were somewhat noisy and slightly labored.

The diagnosis was considered doubtful, in view of the uncertain history. Laryngeal diphtheria, beginning pneumonia, and a foreign body in the respiratory tract were the three possibilities considered.

Under chloroform narcosis, a Brünig tube was passed into the larynx on February 3. The larynx and upper part of the trachea were free from any foreign body. During the examination large lumps of mucopus were coughed up into the tube almost constantly. A severe attack of dyspnea ensued, during which the tube was withdrawn covered with pus. Culture showed pneumococci. On account of the patient's poor condition and the uncertainty of diagnosis, the operation was discontinued, and the child returned to the ward.

During the next four or five days the patient suffered from a diffuse bronchitis, with the characteristic physical signs. The temperature reached normal on February 8.

*Reported before the New York Academy of Medicine, Section on Laryngology, March 26, 1913.

At this time physical examination of the chest elicited pronounced dulness over the right lung, especially in front, with diminished breath sounds on the right side. The *x*-ray picture was negative. The child now began to suffer from attacks of severe coughing, attended by considerable dyspnea. On February 11, eight days after admission to the hospital, feeling reasonably certain that we were dealing with a foreign body in the right bronchus, under chloroform narcosis we again prepared to pass a bronchoscopic tube, assisted by Dr. MacKenty, Dr. Phelps, and the house staff. As soon as the tube reached the epiglottis, the child was seized with a violent coughing spell, choked, stopped breathing, and became deeply cyanosed. The tube was immediately withdrawn from the mouth, and a quick tracheotomy performed, barely in time to save the boy's life.

Through the tracheal opening the trachea and bronchi were then explored with the bronchoscope. The tube entered with ease the trachea and the left bronchus, both of which were free. The right bronchus, on the contrary, could not be entered for any considerable distance by the tube, owing to the inflamed and swollen character of its mucosal lining. The bronchoscope was then passed through the tracheal opening up toward the larynx. The tube quickly filled with blood and mucus. As the suction pump failed to clear out the blood, the tube was withdrawn, and cleansed with a cotton applicator. One half of a peanut, broken into two pieces, was pushed out of the tube. The child was not in especially good condition, and the operation was discontinued after the insertion of a tracheal canula, which was allowed to remain for forty-eight hours.

During the next six days the child suffered from a bronchopneumonia involving both lungs, from which he made a good recovery.

On February 18 the temperature, which had been normal for twenty-four hours, suddenly shot up to over 104°, and exhibited this characteristic every forty-eight hours. Careful search of the blood failed to disclose any malarial plasmodia. In view of the characteristic malarial temperature and the fact that the child's home was at Mount Vernon, N. Y., he was given quinine, with prompt subsidence of the fever.

On March 5 the child was discharged from the hospital. Two days later the tracheal wound was completely closed.

We believe that during the second narcosis, owing to the relaxation induced by the anesthetic, the foreign body was dislodged from its position in the right bronchus by the attack of coughing. It was then carried to the upper part of the trachea, just below the vocal cords, where it plugged the glottis and induced the almost fatal choking attack which necessitated tracheotomy.

Pituitary Extract in the Treatment of Hemoptysis.—M. E. Rist reported at the Société Médicale des Hôpitaux that he had obtained excellent results in the treatment of hemoptysis by means of the intravenous injection of pituitary extract. One-half cubic centimeter of the extract, representing one decigram of the fresh substance, is the dose injected by the author into a vein at the bend of the elbow. The hemostatic action is generally immediate. A single injection suffices to arrest a profuse and rebellious pulmonary hemorrhage. No other remedy has an effect as rapid and as lasting.—*Le Bulletin Médical.*

THE BACILLUS PERTUSSIS.

It was over a year ago that we had occasion to call attention to the vaccine treatment of pertussis which had apparently exercised a favorable influence over the course of the disease in a number of instances. At that time the Bordet-Gengou bacillus had been found constantly in certain stages of the disease and complement fixation tests with this organism were fairly constantly positive. Whether this bacillus was the true causative agent or merely a secondary invader had not been definitely determined. Of late, however, evidence to this end has become conclusive. Mallory and Horner (*Journal of Medical Research*, XXVII, 115, 1912) at first demonstrated "that the primary essential lesion of whooping-cough consists in the presence of masses of minute bacilli between the cilia of the epithelial cells lining the trachea and bronchi. Their action is chiefly mechanical; they interfere with the normal movements of the cilia by sticking them together; in this way the microorganisms furnish a continual irritation which results in the symptoms peculiar to the disease." They used this lesion as a criterion in their later animal experimentation, and they report now some very important results (*Journal of Medical Research*, XXVII, 391, 1913).

It had previously been demonstrated that puppies were susceptible to the disease. These animals were inoculated intratracheally with sputum from patients in the active stage of the disease, and when killed six weeks later the characteristic lesion was found in the trachea. This lesion in all the infected animals corresponds in every way with that found in man. Sections show clearly that the cilia are not destroyed and that the cells are not injured in any noticeable way. Pure cultures of the organism were then obtained from the sputum of suitable patients and a culture of the original Bordet-Gengou strain was used for comparison and control. They corresponded in every way. The authors inoculated several puppies and rabbits with these pure cultures by injecting them into either the nares or the trachea. In practically every instance they were able to demonstrate the characteristic lesion in the trachea of the animal and in several instances were able to recover the organism, not only from the trachea but also from the nares. It is interesting to note that normal puppies were readily infected if kept in more or less intimate contact with inoculated animals.

By this work all the demands of Koch's laws are satisfied and the *Bacillus pertussis* of Bordet and Gengou is definitely and conclusively proven to be the etiological factor in whooping-cough. These findings should not only stimulate investigation of the vaccine treatment of the disease, a treatment which has already met with a certain measure of success, but should also arouse the attempt to find a specific antibody which might be suitable for therapeutic purposes. In animals and man the bacilli diminish and finally disappear in the course of a few weeks and the complement deviation tests are regularly positive, two observations which would indicate the presence of some antibody. It should be a fruitful field and it is to be hoped that it will not be neglected.

THE SEGREGATION OF MENTALLY DEFECTIVE CHILDREN.

The medical profession is now fully aroused to the realization of the presence in the community of a large number of mentally defective children and adults. It is estimated that there is one feebleminded individual to every three hundred normal ones, which would mean about three hundred thousand in the United States, and that it costs about $200 per annum to maintain each one of them. This is a large increase over previous estimates. To what this increase may be ascribed is not yet definitely settled. The contention that it is due to the influx of a large number of alien individuals is not sufficiently demonstrated to warrant leaving the investigations there. On the other hand some investigators deny that there is any real increase at all, but maintain that the increase is only apparent, and due entirely to advanced knowledge of the subject and refinements in diagnosis, and that many persons are regarded as feebleminded who would have escaped this classification, when knowledge on the subject was less highly specialized. Moreover, the progress of civilization requires a higher standard of mental development and acuity to bring one on the normal side of the line—"in the face of the profoundly intellectual we are all more or less feebleminded."

There is, however, a degree of arrest of mental development in which there is little doubt that the arrest is permanent, definite, and not relative, and that it is incurable or allows of no progress beyond a certain point. These persons are best treated when segregated in institutions, where they can be properly protected and cared for, and whereby the public will be relieved of the danger of having such defectives propagate their kind. But it must not be forgotten that while the greatest number of defectives are such because of arrest in development of some part of their central nervous system, there are many children who answer the same tests of a measuring scale of intelligence that actually defective children do, but who are yet not real defectives, being merely retarded in a greater or lesser degree from the lack of physical opportunity to develop their mentality; that is, from physical defects

of speech, sight, and hearing, which retard or even prevent their mental development by obstructing the opportunities for acquiring, through these channels, the stimuli that naturally flow through them. With the correction of these defects, the normal mind becomes sensitive to the stimulation of environment and education, whereas the actual lack of gray cells in the feebleminded is affected by no amount of stimulation, and will never develop. A child, then, previously defective under the Binet-Simon scale or under any of its modifications for measuring intelligence, will, after appropriate medical treatment, rise to its own level, or even beyond it. Hence the necessity of submitting all children suspected of being mentally defective to a special medical examination—not merely the general one given to all children—with the view of determining physical defects from the standpoint of mental development.

The practice that has sprung up since the introduction of the measuring scales for intelligence, of delegating the mental examination to teachers engaged in the work of training defectives, is very harmful, and may discredit the whole science as being a legitimate branch of the medical sciences. Psychiatry, of whatever branch, requires a very broad training, a broader one than that obtained in the study of either pedagogy or psychology. A training in psychology alone is not sufficient any more than a training in physiology alone is sufficient to fit a man for the practice of medicine. Psychology is the study of the workings of the normal mind, psychiatry is the study of the pathological processes. The former should be studied in preparation for the latter. Besides, psychiatry requires a very broad general and medical training, and a special training in diseases and defects of the mind. The lay workers have an important part in this science, but it is entirely in the teaching and training of those set down as permanently defective by the psychiatrist.

In no case should a child be segregated in an institution for the mentally defective after a test merely with a measuring scale, mechanically carried out by a lay worker. Only after a thorough medical and mental examination by the physician, and after a probationary period spent under observation by a physician, should a child be relegated to the class of the mentally defective. For a child retarded or defective from some physical impediment who is put with those actually defective, will soon sink to their level. Environment has almost as much to do with development as heredity, and even a good hereditary constitution can sink under a depressing environment.

VEGETARIANISM.

Although vegetarianism has made considerable headway during recent years, several noted authorities on the physiology of digestion have firmly set their faces against the practice, that is to say, for the ordinary normal civilized individual. There is little doubt that frequently, in fact, more often than not, a person eats more than he needs and does not eat the food most suitable to the requirements. Moreover, the man or woman who leads a sedentary life does not need the quantity or kind of food that one who works hard at manual labor in the open air can digest and assimilate. And again the older a person becomes the less he is able to digest to the advantage of his physical and mental powers. But all this does not mean, according to the opponents of vegetarianism, that he or she is to cut meat out wholly from the diet, even if engaged in sedentary work or if the digestive mechanism is becoming somewhat worn by use or abuse. Professor Ernest Starling points out in his "Human Physiology" that the fact that in many cases greater economy and efficiency of nutrition are attained by diminishing the protein of the diet affords no argument for accepting or rejecting any given class of foods. Thus the normal requirements of the individual can be obtained by the administration of a diet containing meat, eggs, vegetables, and cereals, or by a diet derived entirely from the vegetable kingdom.

A purely vegetable diet is rendered possible in civilized countries by the ease with which the products from warmer climates can be obtained. A diet composed only of the products of temperate climates would tend to be deficient in fats and oils. In such climates it is therefore necessary to import the oily fruits grown in warmer lands, or to supplement the diet with such animal food as milk or butter or eggs. In drawing up a purely vegetarian diet it is important to remember that its constituents, especially its protein, are digested with greater difficulty than the corresponding ingredients in animal food. A larger quantity therefore has to be given in a vegetable diet in order to allow for the greater loss by the feces. Any general reform of diet which may be indicated by recent physiological experiments would seem to be rather in the direction of limitation of the quantity of different articles of food, perhaps especially of those rich in protein, than in a limitation to foods obtained from the animal or vegetable kingdom. In certain individuals the increased bulk of indigestible residue which is afforded on a vegetarian diet presents a distinct advantage, since it serves to promote peristalsis and the normal evacuation of the large bowel. Starling concludes that there is no scientific evidence that for the ordinary person any advantage is to be gained by adherence to a strictly vegetarian diet.

Professor Gautier, a well-known French authority on dietetics, recently made a vigorous attack on vegetarianism in a Sorbonne lecture on the value of various food stuffs. In the course of his remarks he gave it as his opinion that vegetarianism in no way meets the requirements of the activities of modern nations, and as a fixed regimen is anything but desirable, as it reduces the energy, weakens the will power, and lessens the capacity for prompt decision.

It is likely, nay obvious, that the well-to-do individual generally eats more than is good for him, and when he does this, he is as likely to injure his digestive system by limiting his diet to vegetables as the person who eats too much meat—rather, Starling thinks, he is more apt to do so. A mixed diet, taken in moderation, will doubtless suit the healthy civilized man the best. Of course, the per-

sonal equation must always be taken into consideration, and when a person has arrived at the age of discretion, he should begin to be the most reliable judge as to what kind of food and how much is best adapted to his requirements and to his digestive powers. A person will learn in the school of bitter experience what he should eat and what he should not eat, and if he does not so learn, he will soon go the way of the unfit.

Country Schools and Rural Sanitation.

Several public health reports have been issued recently dealing with the unsanitary conditions of rural districts in the Southern States, especially in relation to the widespread existence of hookworm disease. Chas. Wardell Stiles, in reprint No. 46, refers to these conditions, but more particularly with regard to the influence exerted by the country school teacher. He defends the teachers from the aspersions so frequently cast against them nowadays and points out the narrow-mindedness of their critics who think only of efficiency in teaching. The true facts are that the teacher is paid an insufficient salary for the noblest of all work, and at the same time is compelled to submit to unsanitary conditions which occasionally seriously injure her health and shorten her life. Suggestions as to improvements in the sanitary surroundings usually fall on deaf ears. This is unfortunate for the public school teacher. But with all this she is the greatest civilizing influence today in the rural districts. It cannot be denied that a better educated class of teachers might be obtained if they were paid better salaries, but Stiles would suggest to their critics that they will probably be able to retain their young women a year or two longer if they improve the present indecent and unsanitary conditions under which these young women have to work. Further, these teachers will certainly have more success in their pedagogic efforts if the sanitary conditions surrounding the schools are improved to a point where the country school will not form, as it forms today, the great disease-spreading center for rural and semirural communities.

News of the Week.

Vital Statistics.—The mortality tables of the principal cities of the world for 1912, which have just been issued give the record for a low death rate to Amsterdam which reported 10.94 deaths per one thousand of population. Charlottenburg and Dusseldorf are next, with 11.21 and 11.94 respectively, though both of these cities have a comparatively high infant mortality. Of the larger cities, London had a death rate of 13.52, Hamburg of 13.58, New York of 14.11, Berlin of 14.39, and Paris of 16.38. In the United States, Minneapolis had the lowest death rate, 10.57 per thousand, while Washington, Baltimore, and New Orleans reported rates of over 17 per thousand, the presence of large numbers of negroes in these cities being given as the cause.

In the table of infant mortality, Stockholm has the lowest rate, 82 per thousand of births, London is next with 90, and New York has 105, the lowest in its history. Berlin has a high infant mortality, 142.9 per thousand.

New Marriage Law.—By the action of its State Legislature on June 25, Pennsylvania became the first State to adopt what is called a "eugenic marriage" law. The measure which had the support of the State Medical Societies, prohibits the issuance of marriage licenses to persons afflicted with a transmissible disease; specifies that a license shall not be issued when either of the contracting parties is an imbecile or is under guardianship as a person of unsound mind; provides that no male who is or has been within five years an inmate of any county asylum or home for indigent persons shall be permitted to marry unless it appears that the cause of such a condition has been removed and that the person has become physically able to support a family, and stipulates that marriage licenses shall not be granted to persons under the influence of intoxicating liquors or of narcotics.

Nurses' Home.—The Woman's Hospital, New York, will shortly erect a seven-story building to be used as a home for nurses adjoining the hospital building on the south side of 110th Street. The building will have a frontage of fifty feet, and the façade will be of brick and granite. There will be a roof garden and a solarium for the nurses. The estimated cost is $125,000.

Condemn Friedmann Treatment.—At a meeting of the Canadian Medical Association in Ottawa on June 26, a committee appointed by the Canadian Association for the Prevention of Tuberculosis to investigate the cases inoculated by Dr. Friedman in Montreal, Ottawa, Toronto, and London, made its report. The committee found that the results had been disappointing and the claims made for the remedy had not been proved, and that nothing had been found to justify any confidence in the remedy.

International Conference for Cancer Research.—At the meetings of the Third International Conference for Cancer Research to be held in Brussels from August 1 to 5, 1913, the following topics will be considered:

1. The use of physicochemical processes in the therapeutics of cancer. The use of chemical agents after radical operations. 2. Vaccination against malignant growths. 3. Statistics on cancerous disease. Local propagation. 4. Prophylactic institutions for cancerous disease. 5. The care of those afflicted with cancer, and the necessary training of a staff. 6. The present situation of the study of cancer and of the fight against cancer in different countries. Presentation of books, pamphlets, and tracts for the medical profession and literature to educate the people on these subjects.

International Congress of Surgery. — The Fourth Congress of the International Society of Surgeons will be held in New York on April 14 to 18, 1914, under the presidency of Prof. A. Depage of Brussels. Three subjects have been announced for discussion: 1. Gastric and duodenal ulcers (de Quervain, Hartmann, Lecène, Mayo, Moynihan, Payr); 2. Grafts and transplantations (Carrel, Lexer, Morestin, Ullmann, Villard); 3. Technique of amputation (Binnie, Ceci, Durand, Kusmik, Ranzi, Witzel). The sessions of the congress are public, but participation in the discussions is limited to the members and the discussion will be confined strictly to the topic of the day. Information in regard to the program may be obtained from Dr. L. Mayer, Secretary-General, 72 Rue de la Loi, Brussels.

School for Health Officers.—Under the auspices of the Kansas State Board of Health, the Medical School of the University of Kansas conducted a

series of lectures on sanitation and public health from June 23 to 28. The course was open without charge to all health officers, physicians, and medical students of the State of Kansas.

Health of the Canal Zone.—The report of the department of sanitation of the Isthmian Canal Commission for the month of April shows that there was during the month a total of 51 deaths from all causes among employees, of which 24 were due to disease and 27 to violence. This gives a death rate for the month of 10.29 per thousand, which compares favorably with previous years. The annual average death rate per thousand in the cities of Panama and Colon and the Canal Zone, including employees and civil population, was 21.18 for the month, while for the same month of last year it was only 17.21. Of the total deaths among employees, 5 were due to lobar pneumonia, 3 to organic heart disease, and 7 to tuberculosis. No cases of yellow fever, smallpox, or plague originated on or were brought to the Isthmus during the month.

Public Health Council.—Governor Sulzer on June 27, announced the personnel of the new Public Health Council, which under the recently enacted health law will have charge of the formulating of sanitary regulations for New York State. It is composed as follows: Dr. Hermann M. Biggs, New York, chairman; Dr. Simon Flexner, New York; Mr. Henry N. Ogden, New York; Mrs. Elmer Blair, Albany; Mr. Homer Folks, New York, and Dr. Edwin Clark, Buffalo. Commissioner of Health Porter will continue in office until December 31, 1913, when Gov. Sulzer's term expires. The Legislature has given the Health Department an additional appropriation of $125,000, to meet the salaries and expenses called for under the present plan of enlargement. Twenty-seven new officials are to be appointed.

Medical Examinations in Alaska.—The Alaska Territorial Legislature has passed a Medical Practice bill, providing for examinations to be held at Juneau, in January and July of each year. The fee is $25.00.

Personals.—Dr. Elias Potter Lyon, dean of the St. Louis University School of Medicine, has been chosen dean of the College of Medicine and Surgery of the University of Minnesota, to succeed Dr. F. F. Westbrook, resigned.

St. Louis University School of Medicine, has been appointed by Governor Foss to represent the State of Massachusetts at the Third International Conference on Cancer in Brussels, and at the Seventeenth International Medical Congress in London.

Dr. Rupert Blue, Surgeon General, United States Public Health Service, received the honorary degree of Doctor of Public Health from the University of Michigan on June 26.

Dr. Knopf's Work on "Tuberculosis as a Disease of the Masses and How to Combat it."—Dr. Balkrishna Sharma of Delhi, India, has recently made a Hindi translation of Dr. S. Adolphus Knopf's international prize essay on tuberculosis. Dr. Balkrishna has been fortunate enough to find a philanthropic publisher so that the essay can be retailed at 5 annas (about 10 cents). In view of the great prevalence of tuberculosis in India and the fact that the Hindi language is spoken by more than eighty million people, the desire to educate the masses in the combat of tuberculosis in that part of the world is a gratifying sign of the universal progress of the anti-tuberculosis campaign. A new issue of the Seventh American edition of this work has just come out, so that, since the appearance of the original first German edition in 1900, there have appeared in all, including this Hindi and the recently issued French-Canadian translation, 36 different editions in various languages spoken in Europe, America, and Asia.

Gifts to Charities.—By the will of the late Mr. Lyle Reid of Jersey City, N. J., the sum of $2,000 is bequeathed to Christ Hospital of that city.

The following bequests are contained in the will of the late Mr. Karl Hutter of New York: the German Hospital, Brooklyn, $10,000; the Marienheim, Brooklyn, $20,000; and the German Hospital, New York, one-fourth of the residuary estate, the value of which is not stated.

Dr. Hartley's Estate.—Princeton University is the chief beneficiary under the will of the late Dr. Frank Hartley, who left an estate estimated at about $200,000. The bulk of this after the death of his wife is to go to Princeton and be used to create the Hartley Fund, the income of which is to be paid out in scholarships to needy students. Dr. Hartley also left gifts of $5,000 each to the New York Hospital to endow a bed in the surgical ward, and to Princeton to endow a bed in the Isabella McCosh Infirmary. Another bequest of $15,000 was made to Bowdoin College to establish the John F. Hartley scholarship in memory of his father, for the aid of graduates of the college desiring to study law.

Obituary Notes.—Dr. William Henry Clowminzer of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1891, a member of the Long Island Medical Society, and physician to the Bedford Hospital and Dispensary, died at his home on June 21, aged 46 years.

Dr. Edwin Augustine Kemp of Lonsdale, R. I., a graduate of the University of Vermont College of Medicine, Burlington, in 1862, died on June 12, after a long illness, aged 80 years.

Dr. George William Johnson of Charleston, S. C., a graduate of the Medical College of the State of South Carolina in 1911, died at his home after a brief illness, on June 12, aged 26 years.

Dr. Wingo Williams of Fort Worth, Tex., a graduate of the University of Texas, Medical Department, Galveston, in 1913—only three weeks ago—died in Philadelphia from scarlet fever contracted while on duty in the Municipal Hospital in that city, on June 18.

Dr. Richard Fletcher Van Housen of New York, a graduate of the Albany Medical College in 1895, a member of the New York State and County Medical Societies, and adjunct physician to Seney Hospital Out-Patient Department, died at his home from Bright's disease, after a long illness, on June 16, aged 46 years.

Dr. Robert Simonton Young of Concord, N. C., a graduate of the New York University Medical College in 1881, and a member of the American Medical Association and of the New York State and Cabarrus County Medical Societies, died suddenly on June 18, aged 52 years.

Dr. John Early of Grant City, Mo., a graduate of the St. Joseph Hospital Medical College, St. Joseph, in 1857, died at his home on June 17, aged 73 years.

Dr. Martin Luther Bruce of Brattleboro, Vt., a graduate of the University of Vermont Medical College in 1872, died at his home on June 7, aged 68 years.

Correspondence.

THE BULGARIAN BACILLUS IN DIABETES.

To the Editor of The Medical Record:

Sir:—I have read with great interest the report in your issue of June 14 of failures in the use of the cultures of *Bacillus bulgaricus* in the treatment of glycosuria. It seems to me from a careful perusal of Dr. Blodgett's report, that he, as the majority of the men who have met with adverse results, looks upon the bacillus as an antitoxin, instead of considering it as an adjunct in aiding the proper metabolism of the carbohydrates, as I have attempted to set forth in my report of Jan. 25, 1913. It appears that they look upon the bacillus as a specific and entirely ignore the diet, permitting that kind of food which I consider is especially harmful in diabetes. If we consider the condition due to an autointoxication, as I do, why give the cultures of *Bacillus bulgaricus* if we persist in giving those articles of diet that help to keep up the autointoxication, as fish, cheese, cabbage, etc.? On the other hand, if we are to ignore the theory that an autotoxemia is responsible for the condition and consider only the inability of the economy to tolerate carbohydrates, the mere use of *Bacillus bulgaricus* surely does not mean that one can give his patients all the carbohydrates he wants from 6 oz. of green peas at a time to pure sugar, as set forth in Dr. Blodgett's report. It is true that some of the carbohydrates or foods rich in carbohydrates are tolerated by the diabetic more than others, as oatmeal (von Noorden) and rice (von Dühring), but that does not mean that all the carbohydrates are tolerated and in any quantity simply because we happen to give the patients cultures of *Bacillus bulgaricus*.

As I have set forth in my previous article, all that this bacillus does is to destroy putrefaction and slow down the time of carbohydrate digestion, causing it to be absorbed more slowly so that more carbohydrate is tolerated. The affinity for sugars is very much greater in the diabetic than in the normal healthy person. The carbohydrates are rapidly converted into glucose and absorbed by the body, and excreted as such by the kidneys. To prove this I had a series of examinations made on stools from normal people and those from diabetics. In normal stools we occasionally came across some starch granules and very rarely got a reduction of Benedict's solution. In the diabetic stools we never got a reaction for either starch or sugar, showing that the digestion, conversion, and absorption of carbohydrates are complete and perfect. If the above is true then we must exercise some judgment in the selection of food for a diabetic. As for the use of fish, I have also permitted my patients to use fish in various forms and found that this almost always increased autointoxication and consequently the amount of sugar.

Now let us see what the patients in Dr. Blodgett's report received in the way of diet. They almost all received fish in some form; some had onions, cheese, nuts, cabbage, tomatoes—articles of diet that should never be permitted; a few were allowed all the milk they wished to drink, notwithstanding that milk has 4.5 per cent. lactose. Case No. 2 received 6 oz. green peas at a time or about 1 oz. of pure carbohydrates. Now when we come to Cases 4, 5 and 6—grave cases of acidosis—all received pure sugar, from 1 to 1½ ozs. a day. Why they received sugar in preference to other treatment for combating the acidosis is beyond me. Most of us know that in severe cases, where the diet is free and sugars are ingested, the patients rapidly fall into a state of acidosis and die in coma. Why sugar should be given to combat the acidosis I do not know. I do know that I have had a great number of patients who had marked acetone, diacetic and oxybutyric acid in the urine who were saved and those substances were eradicated from the urine by other means than giving sugar. And I am sure that has been the experience of other men. Only in Case 5 did Dr. Blodgett make an attempt to give the patient sodium bicarbonate, I suppose with the idea of neutralizing the acidosis, but then she received 10 grains a day.

Philip Horowitz, M.D.

65 West Seventy-third Street.

HIGH BLOOD PRESSURE AND HARDENED ARTERIES.

To the Editor of the Medical Record:

Sir:—With the daily use of the sphygmomanometer in medical practice there has come another abuse nearly equal to the furore for abdominal section in appendicitis, and foolish doing and exaggeration in pulmonary tuberculosis. Everywhere at present, in talk and in print, we meet with high blood pressure, hardened arteries. Advanced knowledge is good, always presuming it is true and lasting—and also that it be used with common sense and controlled by sympathy for the sufferer in mind or body. In hospitals, it is well for students to be instructed as to novel findings. It is also well that their present and prospective value may be rightly appreciated. When, however, we find the advanced methods of research becoming the daily routine of the practitioner, they are a great evil in more ways than one.

To begin with, physical instruments, especially those which are accurate and delicate can be used with precision and value only by one who is specially skilled. This skill comes solely with continued doing and multiplied opportunity of varied instances. Again, to translate rightly, the value of its showing requires great knowledge and thoughtful consideration of different problems involved. Further, and lamentable fact, which is more and more notable, many people are made apprehensive and unhappy by the use of instruments of which they know little or nothing, and to whose use undue value is attached.

The harm to-day of exaggerated specialism is, to my mind, enormous, and there seems little prospect of arresting it. The man with wide, sober vision, who is able and willing to give every branch in medicine or surgery its proper importance in the makeup and marking of the bodily machine, is put aside as out of date or ignorant. And yet he represents the only real wisdom which should also be the ever-guiding hand.

We know surely after several years of observation that there is no medication of value in arteriosclerosis (syphilis excepted) except in the correction of bad causative habits. We also know that drugs to lower high pulse tension, must be used with great caution, and only when immediate danger threatens, or there is great discomfort. When one or the other is relieved, mere drugging should cease. Not so, with excesses of food, alcohol, work, worry. These should all be lessened and

continuously. Blood pressure lowered in the former way is temporary and sometimes in so doing harm results to cardiac power. In the latter way, good alone results. Whenever blood pressure is high and remains so permanently, despite efforts to diminish it, we must conclude that it is truly conservative and it is both unwise and foolish to attempt to lessen it. Frequently we have seen high pressure lowered and the patient made worse by reason of a weakened heart. Add to this, what I have also witnessed, the case of a patient whose daily watching the rise or fall of the mercury tube shortened his life, and during its duration, made him, as it were, "die daily" from nervous fright. The pursuit of science thus easily separates itself from the cause of humanity.

Beverley Robinson, M.D.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

FANCY FAIR FOR THE LONDON HOSPITAL—CHYLOUS AND CHYLIFORM EFFUSIONS—TENURE OF MEDICAL OFFICERS OF HEALTH—SIR V. HOUSLEY AND THE HOME SECRETARY—OBITUARY.

London, June 13.

The needs of the London Hospital are always pressing, and it is said have been greatly increased by the Insurance Act. To afford it some extra assistance a number of aristocratic ladies organized a fancy fair, on which they bestowed the name of "Noah's Ark." They have been at work for it a long time, and it has been held this week at the Royal Albert Hall, and promises to produce a considerable sum for the hospital, as it has been conducted on a splendid scale and the organizing ladies have been by no means afraid to solicit help from every one they could venture to approach. Queen Alexandra was patroness of the fair, and on the opening day attended. Her majesty was accompanied by the Empress Marie Féodorovna of Russia, and the Princess Victoria. At one stall Princess Louise, Duchess of Argyll, presided, and the royal visitors examined the display with interest and made many purchases.

Mr. Louis Wain was called to the royal box to draw some of his humorous cats, which were purchased by Queen Alexandra and the Empress. Yesterday the Crown Prince and Crown Princess of Sweden visited the fair and were accompanied by Princess Victoria Patricia of Connaught. You may remember that the London Hospital is the largest in the metropolis, and is situated in the East End, and serves the poorest of the population. It is to be hoped that these efforts of its richer supporters will be followed by an increased subscription list.

Chylous and chyliform effusions are perhaps more frequent than is generally supposed, if one judge by the number of cases cited at the Medical Section (R. S. M.) last month. D. H. A. Lediard began the discussion by describing a case in a young man of 18 who had what was held by all who saw him, abdominal tuberculosis, for some twelve years, and ascites for half that time. Drainage was advised, and a large quantity of a milky fluid evacuated of sp. gr. 1005, containing 6 per 1,000 albumen and not 0.2 per cent. fat; no cellular elements, no blood, no pus. Only temporary improvement followed, and he died eventually with brain symptoms. At the post mortem 65 ounces of chylous fluid was found free in the abdominal cavity, more on the right side than the left. Tubercle was scattered throughout the system —spleen, liver, kidneys, membranes of brain, mesenteric glands, intestinal peritoneum, all were involved. In another case the glands in the neck were much enlarged on both sides, the patient being a girl of 16 who had undergone two operations, one for excision of these glands, the other for those in the left axilla. An acute attack of pain in the abdomen and vomiting led to puncture of the peritoneum when chylous fluid was removed. It was suggested that the enlarged glands pressed on the thoracic duct. Dr. Lediard mentioned yet another case in a woman with mitral disease and liver affection with ascites. On tapping, chyliform fluid was evacuated.

Mr. Mackenzie Wallis discussed the chemical differences between chylous and chyliform fluids, and pointed out that mixed forms might be obtained from a single patient. The specific gravity, total solids and ash should be ascertained as soon as possible after withdrawal. The presence of lecithin was important. The nature of the fat served to distinguish normal from pathological human fat. Sugar was not so important, as it might be present or absent in either variety of these fluids. Dr. Wallis referred to an article in the *Quarterly Journal of Medicine,* in which all the cases were recorded in the literature—174 altogether. He objected to Quincke's classification founded upon the varying amount of fat found, and proposed to recognize only two groups, which he termed chylous and pseudochylous. In the former he put fluids due to injury or disease of the chyle vessels with escape from the lacteals. The pseudochylous included fluids in the serous cavities in which opalescence was only partly due to fat, other ingredients being concerned. In chylous cases reaccumulation took place more rapidly than in the other group. The pseudochylous fluid was pure white, in contrast to the yellowish, and it diminished in quantity after several tappings. Moreover, the pseudo was odorless, as against the smell of the chylous, which resembled ingested food due to the fat contained. Out of the recorded cases forty-two were complicated with pleural milky effusion, two with pericardial; Dr. Ryffel one, with chronic nephritis, corresponding with Dr. Wallis' pseudo group. The other was more obscure. Milky fluid was found in the thorax, but the post mortem did not enable him to determine its origin. It contained some fat globules, but not enough to account for the opalescence.

The grievance of medical officers of health was raised in Parliament yesterday on the vote for the local board. Some of these officers hold their position on practically life tenure and cannot be dismissed without the consent of the Local Government Board. Others, however, can receive notice from the local authority engaging them, and are thus liable to dismissal by that authority. As it may be a duty to censure the persons employing them, they want some security of tenure, and ask that the consent of the Local Government Board be made essential to every dismissal.

In the House of Commons the Home Secretary was asked if he had laid a complaint about Sir Victor Horsley before the College of Surgeons and refused to give Sir Victor information as to its nature. Mr. McKenna replied that Sir Victor had made certain public statements reflecting on prison

officers. In justice to them he sent the statements and his reply in that house to the college. As to the request of Sir Victor to give him information he referred him to the college. Asked if it would not have been fairer to communicate to Sir Victor before complaining to the college he said no, he sent nothing but what Sir Victor had publicly stated, and his reply in that house, not marked private, and the college could do what they thought proper about furnishing a copy; he had no objection. There could be no secret about statements published in most of the newspapers, and his own statement in that house.

Of course Sir V. Horsley is angry, and writes to the papers his counter statement in terms well charged with talk of "subterranean attacks," "inaccuracy," "secret intrigue," "machinations," and other expressions in which he is an expert. His greatest annoyance appears to be that the college "flatly refused" to supply the documents, though demanded by his solicitor. Further, he suggests that "possibly he may in time become aware" of the charges against him. But really it is strange that he pretends not to know what were his public statements about prison officers and what were the terms of Mr. McKenna's defence of them in the House of Commons. Mr. McKenna has said what he sent were those statements and nothing more.

Dr. L. Forbes Winslow died on Sunday from cardiac failure, aged 69. He had been in failing health for some time, but death was not anticipated. On Saturday night he seemed better than of late. He was the youngest son of Dr. Forbes Winslow, who attained great reputation as a specialist in mental diseases, and he followed in his father's footsteps with success. He graduated as Bachelor of Laws at Cambridge, 1866, M.B. 1870, D.C.L., Oxford, in 1873. He was president of the lunacy section of the Medico-Legal Congress, New York, 1895, and contributed to the journals respecting it. He edited for several years the *Psychological Journal*, and wrote "A Manual of Lunacy," "Mad Humanity," "Fasting and Feeding," "Spiritualistic Madness," "Uncontrollable Drunkenness," and a "Handbook for Attendants on the Insane." He had been a lecturer at Charing Cross Hospital. He was also known as an athlete.

Dr. Edmund Wilkinson Roughton, F.R.C.S., M.D., Surgeon to the Royal Free Hospital, died on the 10th inst., aged 51. He was a Bart's student, and graduated at the London University with distinction, taking the gold medal at the M.B. examination, 1883, and another at his B.S., 1887, and the scholarship in surgery. He also took the gold medal with his M.D. He was demonstrator of anatomy at his own school from 1886 to 1889, warden of St. Mary's Hospital College, 1891-7 and examiner for the Royal Colleges of Physicians and Surgeons in 1896.

The death has also occurred of Dr. Surgeon-General J. Lloyd Thomas, who retired in 1911 in ill health contracted during service in China, for which he received the Order of the Double Dragon. He entered the Royal Naval service in 1884, and served in the Home Fleet and afterwards in the West Indies. He was at Chatham in 1906-8, and in drill ships in 1909-10.

Dr. Geo. Hy. R. Dabbs was found dead in his bed on Tuesday morning. Besides the double qualification in London, he graduated at Aberdeen M.B., M.S., 1867, and M.D., 1868. He then traveled on the continent for a couple of years and afterwards settled in practice in the Isle of Wight. He remained there until 1903, afterward coming to London. Besides being a successful practitioner, and later consultant, Dr. Dabbs was well known in the literary world, as the editor of *My Journal* and as the writer of a number of books and plays. Among them I may mention "Before Good Night," "From Door to Door," "Vectis," "Ugly—a Hospital Dog," "The Ladder of Pain," "The Child Healer."

6. A Case of "Syphilitic Periostitis" Cured by Salicylates. E. H. Goodman.

1. **Diabetes Insipidus and the Polyurias of Hypophyseal Origin.**—H. Cushing discusses this subject in its experimental and clinical aspects. As the result of his investigations he has found that the infundibular lobe contains, in addition to the substance capable of glycogenolysis, a chemical body or hormone capable of eliciting diuresis. Under certain operative conditions which entail posterior lobe manipulations there often occurs a diuretic response, and occasionally an extreme polyuria, whereas a temporary diminution in the excreted urine is apt to follow other operative procedures, requiring an equally long anesthetization. Posterior lobe implants may cause a temporary polyuria, which subsides on the removal of the implanted tissue. Stimulation of the autonomic system of nerves to the gland elicits diuresis. Certain operative procedures, such as separation of the infundibular stalk, and occasionally a simple posterior lobe excision, may call forth a somewhat prolonged polyuria. Certain clinical observations, coupled with the experimental data which have been assembled, suggest to the author not only that the emotional polyurias are in all likelihood the expression of a neurogenic discharge of hypophyseal secretion, but also that the clinical polyurias of longer duration are in many instances merely the symptomatic expression of an internal secretory disturbance brought about by injury or disease involving the hypophyseal neighborhood. Hence, whether or not there actually proves to be a form of polyuria of primary renal origin, one's present conceptions of so-called diabetes insipidus need to be recast, with especial reference to the factor of the secretory activity of the pituitary body and particularly of its posterior lobe.

2. **Diagnosis and Treatment of Diphtheria.**—J. B. Greene emphasizes the following points: The diagnosis of diphtheria depends primarily on finding the organism. A culture should be taken of every sore throat in children, and likewise of suspicious nasal discharges. But in the absence of a positive finding, if the symptoms point to diphtheria, antitoxin should be given. This is particularly important if the symptoms are severe. Much larger doses of antitoxin should be given in diphtheria. Textbooks have been misleading in this respect. Laryngeal cases are serious, partly from mechanical obstruction, requiring prompt relief of the stenosis, and large doses of antitoxin. Intubation in the main is preferable to tracheotomy. Laryngologists should perfect their technique in this operation until it becomes a fairly simple one. Epidemics of diphtheria are kept up largely by "carriers." They should be sought out and isolated, and the abnormality treated. Diseased tonsils and adenoids may require removal.

3. **Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis.**—H. L. Barnes and T. T. Fulton report their experience with this method of treatment in seventeen cases. They believe that while seventeen cases are obviously too few to enable one to form definite conclusions, pneumothorax prolonged the life in twelve or 70 per cent, of the cases. These were, moreover, far advanced and progressive cases. One would expect much better results in unilateral cases and in those less far advanced. Moderately advanced progressive cases in which a high or moderate fever is not controlled within a month or two by rest in bed and in which one can determine in which lung the disease is active, are entitled to a prompt trial of this method, especially as the chance of recovery in these cases is slight under ordinary methods of treatment.

5. **Tuberculosis of the Epididymis.**—J. D. Barney states that in genital tuberculosis the epididymis is the primary focus in the vast majority of cases. Tuberculosis of the epididymis becomes bilateral in 41.6 per cent. of all cases and becomes so within six months of the time of involvement of the first side in 30 per cent. The prostate and vesicles are found to be infected in 75 per cent., this infection occurring in the first six months in 30 per cent. and in the first year in 54 per cent. It is also shown that this infection takes place quite as often in the presence of unilateral as of bilateral epididymitis. The urine is pathological in 43 per cent. of all cases; bladder irritability is found in 35 per cent., and in about half of these it occurs in the first six months. In 33 per cent. tuberculosis, past or present, of organs other than those of the genitourinary tract, is to be expected. The lungs are most often attacked. Clinical observation shows tuberculosis of the testicle in 44 per cent., but the pathologist finds the disease in 66 per cent. and of these 53 per cent. are found infected within six months of the onset of the epididymitis. The records of 67 epididymectomies show that no case has yet returned for orchidectomy. The radical operation is, therefore, rarely necessary. Infection of the first and second epididymis, as well as of prostate and vesicles, seems to be by the blood or lymphatic streams, but it cannot be denied that in some, infection takes place through the vas by an ascending or descending process. The operative mortality of 147 cases is 2.72 per cent., a general miliary tuberculosis being the most common cause of death. As it has been shown that the infection may become widespread in the first six months of the disease operation at the earliest possible date is strongly indicated.

2. **Influenzal Otitis.**—S. MacCuen Smith reports a case of this condition which illustrates the rapid destruction that frequently accompanies an influenzal otitic inflammation, and also forcibly illustrates the almost total absence of suffering by the patient. He calls attention to the fact that even though an early myringotomy had been done, in this particular instance it is doubtful whether the rapid destruction could have been prevented or even modified, for it would seem, in accordance with the findings, that the mastoid process must have been involved simultaneously with the tympanic cavity. Recently the author operated on a patient showing no general symptoms, but presenting equally destructive changes, in which the middle ear gave no evidence of inflammation other than a mild degree of myringitis. In this latter case one probably would be justified in claiming a primary mastoiditis, and yet the author believes that the infection originated in the tympanic cavity and that the mastoid was secondarily involved, the former, on account of the patulous Eustachian tube, being able to drain and recover itself. Five years previously, the same patient had suffered from a suppurative influenzal otitis of the opposite ear, which progressed so rapidly and caused so much necrotic erosion that it was necessary to do a radical operation within the short space of about one week. This case not only illustrates the rapid osseous destruction of an influenzal otitis, but also shows the rapidity with which a brain abscess formation can develop under the destructive influence of this particular type of infection.

5. **Bilateral Nephrolithiasis.**—By O. C. Smith. (See Medical Record, May 31, 1913, page 1006.)

6. **Rapid Cure of Syphilis.**—W. F. Bernart recommends the judicious combination of two intensive methods of treatment for syphilis. He believes that an intravenous injection of mercuric chloride given every day for fifteen days approximately equals the results of an average dose of salvarsan or neosalvarsan, and that the nonantagonistic action of the two, when alternated, might produce a cure for syphilis in a comparatively short period when properly administered. The intravenous form of medication is the only method by which one can overcome the uncertainty of absorption and by which one can obtain a so-called intensive action.

13. **Use of Thermostabile Toxins in Urethral and Bladder Infections.**—F. S. Crockett reports favorable results in the treatment of gonorrhea by means of a modification of the method of autotherapy as recommended by Duncan. He gives subcutaneous injections of 0.1 c.c. of the patient's own raw urine, in conjunction with the usual routine treatment of gonorrhea. The injections produces an ideal reaction, finding expression in the partial or complete cessation of germ activity, but is prone to produce excessive irritation at the point of injection, and is open to the objection that the infecting organism might be carried through the blood stream with the resulting localization of the disease in some other part of the body. The temporary increase of antitoxin makes such an accident less probable. After heating the toxin solution the local reaction disappears or is slight. This led the author to use larger doses, with the result that a few patients appeared to be overloaded with the toxin, so that they failed to improve or actually seemed worse. On discontinuing the toxin these cases would improve markedly in the succeeding few days; which seemed to point to an overwhelming of the patient's resistive powers. This has led the author to use smaller doses, ranging from 0.1 c.c. to 0.5 c.c. as a routine dose for gonorrhea; 0.5 c.c. to 0.1 c.c. in cystitis of old men; and 1 c.c. to 2 c.c. in colon bacillus infections. Clinically he has had the least noticeable improvement in colon infections, and in these would recommend longer periods between treatments.

4. Chronic Nongonorrheal Urethritis.—S. H. Likes and H. Schoenrich report their experience with a form of chronic urethritis of nongonorrheal origin and due to granulations and infiltrations of the anterior urethra. The discharge may be due to various causes—bacteria, prostatic conditions, rheumatism, bladder disease, syphilis, or grippe, and, lastly, to granulations or infiltrations of the urethra, which, in the experience of the authors, outnumber all the others in the list. This type was first described by Otis and Overlander. The usual symptoms consist in a purulent drop collecting at the meatus from time to time, causing little pain but very much anxiety in many cases. When a thorough examination has proved the absence of gonorrheal organisms or other infections and any involvement of the posterior urethra, prostate, etc., one may be certain that the focus is in the anterior urethra. This must be found by the introduction of a bougie à boule of sufficient caliber to stretch the urethral wall so that the granular and infiltrated areas may be felt as rough spots or absolute obstructions. To demonstrate these lesions requires instruments of larger caliber than commonly used. The one thing likely to interfere with their detection is a too small meatus. The treatment advised for the removal of these infiltrations is dilatation by bougies à boule of gradually increasing caliber and ironing out the rough areas with gentle massage made painless by the introduction of cocaine in the passage. A cure will result if the treatment is carried out to a sufficient extent to restore all parts of the anterior urethra to its normal caliber. The intervals between the treatments and the selection of the proper sized bougie depend wholly on the amount of reaction shown by bleeding and pain since the previous treatment. The results obtained by the authors' method of treatment have, they state, been uniformly gratifying.

6. Treatment of Puerperal Infection.—R. T. Gillmore emphasizes the importance of resisting the temptation to give vaginal and uterine douches. The discharge, if any, should not be washed away with an antiseptic, as such a procedure inhibits the antiseptic action of the normal secretions and prevents the phagocytic action of the white blood-cells on the bacteria. In no other disease has the patient's reserve force and resistance such need of conservation.

7. Hot Air and Nascent Iodine in Treatment of Aural and Nasal Conditions.—E. J. Brown states that patients complaining of sore throat and earache from acute pharyngitis have been relieved by a single application of hot air and nascent iodine and have reported the following day that there had been no return of their discomfort. Altogether there is so much advantage and so little of unpleasantness to the patient or inconvenience to the doctor that these conservative methods of treatment ought to commend themselves to the careful physician. The results of these hot-air and nascent iodine treatments seem to be specifically the destruction of the less resistant bacteria and the drying and shrinking of the tissues with the secondary increase of cellular activity and removal of inflammatory products which interfere with drainage. The nascent iodine is generated in a simple apparatus by the heating of iodoform.

8. Serum Diagnosis of Pregnancy.—C. C. W. Judd notes that the early diagnosis of pregnancy, though ordinarily easily made by the patient herself, is sometimes obscure even to the trained physician. Of late years serological methods have been applied. The antitrypsin method was introduced by Frans, Jarish, and others. The antitryptic index is materially increased at the beginning of pregnancy. The complement-fixation test was devised by Fieux and Mauriac, who used a placental extract as antigen. The miostagmin and epiphanin reactions also call for special skill. Recently Abderhalden has promulgated the theory that free chorionic villi of an implanted ovum induce in the maternal organism a reaction which produces digesting ferments for placental tissue. The performance of the test is simple: A fresh placenta is finely ground in a meat chopper, washed entirely free of blood, and then thrown into about a quart of vigorously boiling water, to which it is preferable to add a few drops of acetic acid. After five minutes boiling the water is drained off and the tissue is boiled in a second quart of water for a period of five minutes. This process is repeated as often as is necessary to render the water at the end of five minutes' boiling free from the biuret reaction or a modification of it. Thereafter, the tissue is either drained and thoroughly dried in a desiccator or stored away with a layer of toluene added to prevent putrefaction. The performance of an individual test is simple, consisting substantially in adding one gram of placental tissue to 1.5 c.c. of the fresh hemoglobin-free serum in the dialyzer which has become thoroughly saturated with water. This is thoroughly rinsed in tap-water and partly submerged in 20 c.c. of distilled water in the container, and a layer of toluene is added to both dialyzer and container, the whole being incubated from twelve to sixteen hours. At the end of this time 20 c.c. of the solution in the container are tested for the biuret reaction; if this is positive it indicates that the complex placental protein has been broken down to simpler molecules, which passing through the dialyzer have imparted to the water in the container the biuret reaction. Excluding putrefactive changes, it indicates that the tissue was digested by an enzyme of the patient's serum which is present only in the gravid state and following certain conditions. A negative test is strong evidence that placental tissue is not or has not recently been in the patient's system. The author has used the test in thirty cases and his experience indicates that the reaction when properly performed is a specific one.

9. Experimental Production of Pellagra in the Monkey.—W. H. Harris has succeeded in producing experimentally in the monkey lesions similar to those of human pellagra. From a patient that had died of this disease there were removed tissues of the central nervous system, portions of the skin lesions and tissues of the alimentary and nasopharyngeal tracts, and these were mixed with equal parts of normal saline solution ground together in a mortar and allowed to stand over night in the ice-chest. After coarse filtration the juice was passed through a Berkefeld filter, letter N. This tissue mixture was injected subcutaneously, intravenously, and intracranially in large quantities into a full-grown, normal male monkey. The animal remained normal for several months, after which it developed irregular dark patches on the face, forearms, hands, back and sides of the body. It gradually grew thin and weak and finally died with all the signs of pellagra. The author notes that the animals develop all the essential clinical signs and symptoms together with the pathological picture presented by the disease in man. He concludes that the etiology of pellagra is a filterable virus or a microorganism capable of passing through the pores of certain Berkefeld filters.

4. **The Consumption of Breast Milk.**—D. Forsyth, by the careful weighing of an infant before and after nursing, for a period of seven weeks, gained the impression that the secretion, though becoming ampler with the growth of the child, and to this extent, therefore, being regulated by the demand, varied from day to day and from hour to hour under the influence of maternal factors. Whether the nurse is fed generously or moderately, drinks much milk or little, or takes or abstains from oatmeal, stout, and other reputed galactagogues, no reasonably scientific proof is yet forthcoming that these measures affect the activity of the mammary glands.

6. **Breast Feeding.**—Dr. H. D. Cran states that the serious accidents so commonly attributed to overfeeding by the breast are very exceptional. If the child has taken a little too much milk there is a simple regurgitation, which occurs at that moment after the meal when the stomach contracts and expels the air swallowed with the milk. The stomach of the baby is not a rigid receptacle; its musculature is extensible and its glandular mechanism is quite able to chymify a fairly large quantity of the mother's milk. This does not mean that the weighing machine is never of any use in the control of feeding by the breast. But when a young mother is healthy and has a regular secretion of good milk, and when her baby is likewise normal and drinks well, it is quite useless to weigh the infant frequently. In these circumstances it is sufficient to weigh the child once or twice a week. On the other hand, the methodical use of the weighing machine is indicated as soon as a child on the breast ceases to increase in weight. This will usually show that the secretion of milk is diminishing. The milk of the mother must be administered as an aliment and not measured as a medicine.

10. **The Inorganic Chloride in the Gastric Juice.**—C. Singer concludes that the inorganic chloride present in filtered gastric juice is experimentally found to be in large part the result of a secretory or osmotic process in the stomach wall, and its amount must, therefore, be affected by pathological changes in that wall. Hence, the amount of inorganic chloride in the gastric juice is of pathological and clinical significance.

1. **Clinical Importance of the Sympathetic Nervous System.**—S. A. Kinnier Wilson states that a substance normally secreted by the adrenal medulla passes into the general circulation and maintains the tone of all sympathetically innervated tissue, including other ductless glands. The cells which secrete this substance are embryologically of sympathetic origin. Other substances are produced in the organism which have an antagonizing, neutralizing, or compensating effect when compared with that of the adrenal secretion, and they act rather on the autonomous system. Similarly, many commonly employed therapeutic agents have an action on one or other of these groups. Cocaine, atropine, and caffeine stimulate the sympathetic system and inhibit the autonomic system. Morphine, chloral, and antipyrin inhibit the sympathetic system and stimulate the autonomic system. The linking up of the sympathetic system and the ductless gland system is already proving to be a most important generalization in clinical medicine, and with increasing knowledge this importance will be intensified. There is a large group of diseases known as the angioneuroses, included in which category are such conditions as Raynaud's disease in mild or severe variety, local pallor or "dead finger," local asphyxia, symmetrical gangrene, acroparesthesia, scleroderma, angioneurotic edema, and so on—diseases obviously associated with disturbances of the sympathetic innervation of the vascular system. The frequency with which affections of one or other of the ductless glands are noted in such cases is remarkable. Disease of the thyroid is practically constant in scleroderma. Myxedematous patients constantly complain of feeling cold, and exhibit a malar flush; they often complain of acroparesthesia. In Graves's disease vasomotor irritability is a cardinal feature. Many of the common symptoms of neurasthenia and hysteria are patently of sympathetic origin.

2. **Varieties and Treatment of Chorea.**—F. Langmead points out that four factors contribute to the clinical picture of chorea—namely, erratic movements, psychical disturbance, weakness, and cardiac changes. Any one of these factors may be exaggerated, so that it assumes the dominant part, and in this way four chief forms of chorea occur: (1) Motor, (2) maniacal, (3) paralytic, and (4) cardiac, to which two other forms may be added, (5) latent, and (6) residual. In the motor form the movements take the chief place and may be so severe that the child is unable to sleep or feed and is in danger of death from exhaustion. In the maniacal form the child is seriously ill and has all the appearance of one suffering from severe toxemia. The paralytic form usually supervenes upon one in which the movements have been active. Its most striking feature is the extreme atony of the voluntary muscles. In the cardiac form the heart is seriously affected, while the signs of chorea are proportionately slight. Latent chorea is frequently overlooked. It is characterized by slight fidgetiness and mild psychical unrest, with deterioration of school work, especially in writing and arithmetic, and a weakened mental concentration may be the only indication of chorea. Residual chorea is the name given to a condition which persists, sometimes for several weeks after the disease has ceased to be active. It may have all the features of latent chorea. In the treatment of chorea rest of body and mind is essential. The food should not be restricted, for an ample diet is required to supply the loss of energy which may be very considerable. Sodium salicylate has a special sphere of usefulness. The ill effects of this drug most to be feared are those of acid intoxication. This may be avoided if the bowels are not allowed to be constipated and if sodium bicarbonate is administered at the same time as the salicylate in double the amount. The author does not favor the use of arsenic.

3. **Rules in Artificial Infant Feeding.**—Eustace Smith has formulated three simple rules for the hand feeding of infants. (1) One should take care that the infant is bathed as quickly as possible in hot water, and that his

feet and legs are never allowed to get cold. (2) One should see that a sufficient variety of flavor is contained in the several meals. (3) One should see that the feeding apparatus is absolutely clean, that the food is fresh, and that the sanitary arrangements are generally in good order.

4. Oral Sepsis in General Practice.—A. Mills concludes that oral sepsis is a very prevalent condition, that its effects are definite and far-reaching, and that it forms an important factor in the general health of the community. As many forms of oral sepsis are not associated with pain, the patient rarely complains of the condition of the mouth, and as his general appearance and symptoms are frequently strongly suggestive of anemia, the true state of the case may easily be overlooked. Oral sepsis is a common cause of disorders of the stomach, is directly associated with different forms of arthritis, and either predisposes the individual to, or at times directly gives rise to, suppurative processes in other parts of the body. At critical periods in the life of an individual, as for example at puberty, during pregnancy, at the climacteric, or in the course of a chronic disease, oral sepsis may be the all-important factor in the case.

Berliner klinische Wochenschrift.

June 3 and 10, 1913.

The Abbott Treatment of Scoliosis.—Schanz concludes an article on this subject as follows: The rectification as carried out by Abbott is dangerous. The deforming process, instead of being eliminated or welcomed, is actually fanned into activity. Should we not succeed in neutralizing these effects the end results of Abbott's treatment, however brilliant it may seem, will be an actual aggravation of the disease process. The correction of the deformity by this method may become permanent; but by no means invariably. We may after an Abbott redressement cure, continue to treat the affection according to old established principles, yet even then we may expect to see now and then severe relapses. The trouble with Abbott's as with all other plans is that the cause of the disease is not reached. We have nothing rational to oppose to the disease process. The latter involves a lessened support of the individual vertebræ. These are not equal to the demands made upon them, and the scoliosis then results. We know nothing as to any factors which set up this state of affairs. If we knew of such causal elements, it is difficult to see how they could be reached by treatment. Scoliosis is a disease in which complete recovery may occur. Those treated by Abbott's as by other methods should show us how these vertebræ in some patients gain or regain the ability to support properly the body weight.

Meningism.—Kayser gives a brief general summary of our knowledge of this condition. It is the same as pseudomeningitis and "meningitis without meningitis." The old doctrinaires on inflammation would have said that we have here "irritation without inflammation." It is analogous to peritonism without peritonitis. It comprises the meningeal syndrome: fever, stiff neck, hyperesthesia, headache, Kernig's sign, etc.; but the lumbal punctate is sterile. The differentiation of meningism from meningitis may therefore be made by this test. Nearly all acute, infectious diseases show some percentage of meningism. That for scarlatina is 4 per cent., formerly set down as meningitis, but now recognized by the character of the punctate as chiefly meningism. It appears to be less frequent in some of the other infectious diseases. Strange to relate, it sometimes occurs in helminthiasis. A hysterical type is known. Meningism usually recovers cleanly and does not foreshadow meningitis. The lesions comprise hyperemia and edema, but meninigism may be associated with other intracranial conditions involving the interior of the hemispheres. We know hardly anything of the actual nature of meningism and the treatment is symptomatic.

Lecithin and the Opsonic Index.—Strubell, who has tested many drugs as to their influence on the opsonic index has been investigating organic compounds. No influence was exerted by crystallized albumin or Witte peptone. He was, however, much surprised to find that a lecithin preparation exerts a marked activity in this direction. This was, doubtless, due to lecithin alone, although the special preparation employed contains iron and other ingredients. The index was tested against staphylococci and tubercle bacilli. The action was maintained for an unusually long period.

Surgical Treatment of Pericarditis.—Kolb sums up the recent work in this field. Three forms of intervention are in use. First is puncture, which is also utilizable for diagnosis. Its surgical uses are in pericarditis with effusion, whenever the latter "tampons" the heart and cripples its action. The puncture is also made in effusion of blood into the sac. The operation is not to be undertaken except on the strictest indication on account of the danger of puncturing the heart itself. A puncture which is unwarranted usually results in a pericardiotomy. There is no typical puncture point, and many surgeons have their favorite localities. The fluid should be allowed to come away very deliberately, else the heart may collapse. The second method of intervention is pericardiotomy with resection of the ribs. This is preferred by some surgeons to puncture, but is employed by all for pus in the pericardium. This operation is of course borrowed directly from that in common use for empyema. There are many localities and methods for establishing the thoracic window. One is a simple trepanation of the sternum. The third resource or cardiolysis does not compete with the first two, and is meant solely to separate pericardial adhesions. The credit for planning and executing the operation belongs to Brauer. Some of the adhesions are external and it is naturally these which are most burdensome to the organ and are also accessible to surgery. The intervention is not one of great severity. A thoractomy is performed and the adhesions detached. The number of cardiolyses performed thus far is small. Done as a strictly lifesaving procedure it appears to have accomplished its purpose without injurious consequences.

Lime Treatment in Spasmophilia.—Blühdorn writes of the treatment of lime starvation and spasmophilia in nurslings. After much study he announces that if lime is given in the hope of securing a rapid action it must be administered in very large doses. The best lime salt for the purpose is the uncrystallized chloride. The action of the lime is prompt but transitory. In acute manifestations of spasmophilia its action is valuable, but in convulsions chloral cannot be dispensed with. Lime is well suited for administration over long periods, and spasmophilia may at last be pronounced cured, even if the electric excitability of the muscles never becomes normal. With the lime treatment dieting need not be carried out to the usual extent. Lime is not a specific but simply corrects symptoms.

Duodenal Ulcer.—Küttner states that surgery is now recognized as offering more promise of cure of this condition. Direct excision of the ulcer, theoretically indicated, has thus far been much less employed than resection, for it does not exclude the likelihood of recurrence. Resection if often performed, but, according to the author, when the ulcer is large and hard, suggesting a possible cancerous future. The best procedures are found in elimination of the duodenum by eliminating the duodenum by a gastro-enterostomy. Moynihan, Mayo and Kelling simply fold over the mucosa which is the seat of the ulcer if the latter is on the anterior wall. Wilms transplants a few muscular fibres from the rectus aponeurosis. Von Eiselsberg, in the interest of cure, eliminates the pylorus. In

bleeding Mayo both sutures the ulcer and does gastroenterostomy. In perforation into the peritoneum the operation, whichever one, must be done immediately. Hardly any survive after 48 hours delay. About one-half may be saved if only 24 hours have elapsed.

Münchener medizinische Wochenschrift.

June 10, 1913.

Therapy of Raynaud's Disease.—Schreiber praises Noesske's new method of incising the finger tips and applying intensive aspiration treatment. The cyanotic, blue black and sensitive finger tips have the pulp incised transversely, whereupon a suction cup is applied and strong negative pressure used. The success was astonishing, for within thirty-six hours the fingers appeared normal and were free from pain. The treatments were frequently repeated and after 14 weeks Noesske pronounced the man entirely cured. The case has never relapsed. The author, who is an assistant of Professor Bier, waited for a case of Raynaud's to appear at his clinic. In the first patient, the initial results were as brilliant as in Noesske's case, but this result was not permanent. It seemed natural to test Klapp's hot-air apparatus, and this was used upon the original patient who had had no treatment for some time. Most of her fingers were cyanotic and painful, The working of the hot-air douche also caused much improvement, but this too was short lived. In another patient the hot-air douche gave surprising results which seem to be permanent. It is evident that both methods have good possibilities and the author does not wish to give the impression that Noesske's method is a failure because it did not cure his case.

The Pseudocholecystitis of Typhoid.—Bennecke speaks of the occurrence of pain in the course of typhoid as relatively infrequent. Colicky pains over the gall bladder have led to operations for a cholecystitis which was not found to be present. Nor was there present a subphrenic abscess, the only other condition to be suspected. We have long been led to believe in the frequent occurrence of cholecystitis in typhoid, but this often pursues a latent course and is found only at autopsy. How shall we explain the pain in the false cases? The author concludes as follows: The colicky pains in the gall bladder area will be found to be unassociated with jaundice, nor is there any radiation of pains toward the spine. It will doubtless be found that their existence is due to accidental complications, as acute hepatitis or pleuritis. Either a second disease is present, or else the pains may be due to an anaphylaxis.

Case of Mixed Labor.—Kreisch reports that a woman visited him who had not menstruated for about a year. A child had been looked for at the proper period, but no labor was forthcoming. After having had a few pains cease without any change in the os, she noticed that fetal movements had ceased. Two months elapsed without any unpleasant developments. The abdomen resembled that of a woman at term. No evidences of fetal life. As closed, the diagnosis lay between mixed labor and ectopic pregnancy. When the temperature went up laparotomy was performed. The uterus was found to have very poor muscular development, insufficient for the demands of labor. Macerated fetus and its placenta readily removed. The uterus was extirpated without the adnexa, and the woman made a good recovery.

Deutsche medizinische Wochenschrift.

June 5, 1913.

Radioactive Substances in Riggs's Disease.—Levy states that especially in pyorrhea alveolaris and also in marginal gingivitis, luecoplakia lingualis and ulcerative stomatitis radioactive substances produce results superior to those obtained by the old methods alone. The author, however, warns against overestimation of the new resources; and whoever tries to employ radium rays must determine in advance the accurate dose or be guilty of a technical defect. The action of the rays on the mucosa of the mouth is not as yet understood. In a specimen case of Riggs's disease, involving several incisors and molars, the author, after the removal of all calculus, massaged the gums with radium paste. Teeth became fixed in four weeks.

Paratyphus B.—Knauth, an army surgeon, describes the following syndrome upon which the diagnosis of paratyphus B was made. The bacteriological examination of the stools was positive, which enables him to give the accompanying clinical features. Incubation period very short—in no case over 24 hours. Affection began with chills, vertigo, headache, general prostration. Later nausea, vomiting, malaise, colic, and liquid diarrhea. In no case was there prostration. The patient had the typhoid look, spleen only occasionally enlarged, transverse colon invariably tender, pulse relatively slow, roseola absent. Diarrhea persisted for some days after close of febrile period. The cases were isolated, and no contact infection developed among the doctors and attendants.

Antisepsis and Manual Delivery of the Placenta.—Sievert reports 42 cases of this procedure and arrives at the following conclusions: Antisepsis cannot be dispensed with in obstetrics; asepsis is insufficient, especially for general practitioners and midwives. Acid vaginal irrigations are sometimes of value and rubber gloves are as a rule not needed in obstetrics. Death from hemorrhage after delivery may be prevented by paying attention to the chief predisponents and by compression of the aorta.

Bromine-Borneol Combinations for Disturbances of the Climacteric.—Oppenheim refers to a well-known proprietary drug having the above active constituents, which by reason of its purely sedative action has been tested extensively in disturbances of the climacteric. The results are said to surpass all expectations—every form of nervous disturbance being satisfactorily controlled. The drug however is not supposed to take the place of ovarian extracts in making up for the withdrawal symptoms, and the two should be given whenever the latter are in evidence.

Varicella in Adults.—Kämmerer comments on the note by Krause in the Wochenschrift No. 19 which cites some work of his in this field. The author after complaining that he is referred to as "Kamminer" denies that his work is merely confirmatory of the labors of earlier authors and adds that his critical observations referred to the strong general increase of lymphocytes in the blood. The previous authors on the contrary upheld the claim that only mononuclears are increased. In other words, there was a mononucleosis which corresponds to the same state in variola. The mononucleosis of the French authors was probably an artefact or other result of defective technique.

Strange Use of Formaldehyde.—The lessee of premises, on the expiring of his lease, contended, apparently in good faith, that he had a right to continue in possession. The lessor made an abortive attempt to gain possession of the premises by force, and as a result of this attempt the lessee, with a number of his employees, remained in the building overnight. The premises adjoined a theater occupied by the lessor, and about midnight the lessor's manager bored a hole through the partition separating it from the rooms occupied by the lessee, and, using a bicycle pump, injected about two quarts of formaldehyde solution into the room where the lessee and his employees were dozing. The lessee sued the lessor for damages. The latter's defense that the formaldehyde was used to fumigate the room and only incidentally to make its occupants uncomfortable if they wanted to get out was not sustained, and he was held liable in damages.—Saros v. Avenue Theatre Co., Michigan Supreme Court, 137 N. W. 559.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

Distribution of the Surplus.—The amount of surplus is determined at the end of each year by the process already described. The former practice of deferring dividends for five, ten, fifteen, or twenty years has practically been eliminated and is, moreover, prohibited by law in some states.

The subject of participating and non-participating insurance calls for some attention at this point. The discussion in the preceding chapters has been confined chiefly to the consideration of participating insurance on the ground that the matter of interest, loading, mortality and surplus will be of most interest to those who carry participating policies.

The laws of some states prohibit a home company writing both participating and non-participating insurance, so that, on the whole, the few companies writing both forms of contracts may be disregarded. Under these restrictions mutual companies are obviously confined to the writing of participating contracts, but mixed and stock companies may choose one or the other form.

Participating Insurance.—The great bulk of the participating insurance is issued by mutual and mixed companies, and according to these contracts the surplus belongs solely to the policyholders. The only exception to this arrangement is found in the case of the very few mixed companies in which there is usually a comparatively small amount of capital stock entitled to reasonable and fixed dividends.

The advocates of participating or mutual plans of insurance, in discussing the methods of this system as compared to those of non-participating or stock plans, argue that, as the exact cost of insurance cannot be predetermined, the mutual companies deliberately make an overcharge in order to preserve a healthy margin of absolute safety, and, as this excess is returned in the form of dividends at the end of each year, the companies sell insurance at net cost. The term "dividends" as applied in the case of mutual companies is not a suitable one, as the funds distributed in this way represent the savings and gains from interest, loading, and mortality returned to the owners and are not profits in the sense of returns from ordinary business transactions.

The methods of computing dividends due to each of the numerous classes of policyholders vary in the different companies. The procedures are so complicated and technical that this space is not appropriate for a description of them. It may be sufficient to say that the actuaries of each company have arranged the distribution on a perfectly equitable basis and their methods meet the approval of the insurance departments of the different states.

A policyholder usually holds the option of accepting the dividend in different ways. He may elect at the end of each dividend period to draw the dividend in cash, apply the dividend towards payment of the premium, apply the dividend to the purchase of a paid-up addition to his policy, or let the dividend accumulate at the interest rate assumed by the company in establishing its legal reserve. In comparisons made by the representatives of the mutual companies, tables are exhibited to indicate that the actual cost of insurance on the participating plan with its larger premium and the return of the overcharge becomes less after the first few years than insurance on the non-participating plan with its lower premium and no refunding of the excess.

Non-Participating Insurance.—The great bulk of non-participating insurance is written by stock companies. The policyholders receive no return in the way of dividends, all profits going to the stockholders.

The advantage of this system, as claimed by its representatives, is the low premium. As the net premiums of mutual and stock companies on the same reserve basis are equal, the reduction in the gross premiums is accomplished by charging a smaller percentage of loading. The loading is usually less than sufficient and the companies meet the deficit in expenses and provide for a contingency fund by using for this purpose a part of the excess of interest earned and the saving in mortality. Nevertheless, a certain amount of excess in the loading must be collected by the stock companies, but competition has brought about an effort to compute a fair premium which will allow for a moderate margin of profit on the capital invested.

Comparative Advantages.—After all arguments, it may be said of the best companies of either system that the question becomes one of initial cost to the person who pays the premium. The claim will be surely paid in either case. Perhaps the greatest difference between a mutual and a stock company is the voting right, the control and ownership resting with the policyholders in one form and the stockholders in the other.

Children in Relation to Conservation of Public Health.—Dr. J. S. Lankford, Medical Director San Antonio Life, says that his experience has taught him that the time to begin with conservation work in the interest of public health is with the school child. The business man has not the time and will not give it the time; the mother of the household is too busy with her manifold duties to consider it; but put up to the school children and there is scarcely any limit to what may be accomplished, and when they have been given the truth they will remember it. Everything cannot be accomplished in a few years, but when the children of the public schools—15,000,000 in number—have been taught some idea of the causes of preventable diseases, as for instance, that the mosquito alone is responsible for the infection of malaria and yellow fever, and that extermination of the pest will abolish the disease in a large measure; that the tubercle bacillus shown under a microscope is the cause of consumption, and that care and precaution will in time exterminate tuberculosis; then an impression has been made, and it is to be reasonably supposed these children will grow up to become responsible citizens and will see that laws are passed to aid in the prevention of disease. If life insurance companies would pay more attention to the opportunities afforded them in the public schools, much more good in the line of conservation of public health could be accomplished.—Medical Section, American Life Convention, Hot Springs, February, 1913.

Appendicitis Rating.—Dr. James H. Stowell states that the rating of appendicitis cannot be done properly without inquiring carefully into each individual case, as habits and modes of living are large factors in the production of this trouble. Overeating, overdrinking, poor food, often improperly cooked, all may be contributing causes of appendicitis.

Book Reviews.

THE BIOLOGY OF TUMORS. The Bradshaw Lecture delivered at the Royal College of Surgeons of England, 1912, by C. MANSELL MOULLIN, M.A., M.D. Oxon, F.R.C.S.; Consulting Surgeon to the London Hospital; Member of the Council and recently Vice-President of the Royal College of Surgeons of England; formerly Fellow of Pembroke College and Radcliffe Travelling Fellow, Oxford; and Examiner in Surgery at the Universities of Oxford and Cambridge. Published by request of the Council of the Royal College of Surgeons of England. Price 2 shillings net. London: H. K. Lewis, 1913.

THOSE interested in the subject of cancer will find this Bradshaw Lecture of Mansell Moullin a well-written general review of our present notions concerning the nature of tumors. The writer's general conclusions are that tumors are independent growths not due to parasitic causes and that heredity plays some part in rendering the tissues susceptible to the development of neoplasms. The final paragraphs point out the direction from which we may reasonably expect some therapeutic benefit.

LA BIOLOGIE SYNTHÉTIQUE. Par STÉPHANE LEDUC, Professor à l'école de médecine de Nantes. Avec 118 figures dans le texte. Études de biophysique. Paris: A. Poinat, 1912.

As a contribution to the theory that physical and chemical explanations are sufficient for the interpretation of all the phenomena of life, this small pamphlet is not without interest, though not perhaps so convincing as some of the recent statements of other members of the physical school. Loeb, for instance. The neovitalists are promptly shown the door on the first page, never to reappear in the text. The evidence presented is largely in the form of photographic illustrations to show how closely purely physical phenomena, such as osmosis in mixtures of various inorganic salts, may produce forms resembling very closely cells of tissues, karyokinesis, ciliary structures, and the like. Whether this proves that there is or is not a vital directive force inside of cells, and that cells simply find it convenient to submit to ordinary laws governing symmetry in inorganic solutions, is not very evident. To obviate any criticism as to the immediate acceptance of his ideas, Leduc quotes Kepler's famous saying that his book might very well wait for centuries for a reader since the Creator had been willing to wait thousands of years for so profound a thinker as himself.

DIE GROSSSTADT ARBEIT UND IHRE HYGIENE. By San. Rat. Dr. B. LAGNER, Wiesbaden. Price 1 mark. Marhold: Halle, 1912.

THIS little book deals with the pathological results of work in larger cities and the possibility of their prophylaxis and cure. The author considers conditions in different countries and makes suggestions of acceptable characteristics found in each. The book refers to the middle classes more particularly.

TUBERCULIN IN DIAGNOSIS AND TREATMENT. By FRANCIS MARION POTTENGER, A.M., M.D., LL.D.; Medical Director Pottenger Sanatorium for Diseases of Lungs and Throat, Monrovia, Cal. Price $3.00. St. Louis: Mosby Company, 1913.

THE material for this book, the author states, is from books, men, and experience. The latter far outweighs the former two, for he has treated 2,000 cases with tuberculin. The interpretation of the cutaneous reaction is given and the time limit for active cases is put at twenty-four hours. As to treatment Pottenger says tuberculin offers the best possible chance of cure, but cannot overcome fibrosis, mixed infection, etc., and in the later stages no more should be expected of it "than is possible to be obtained." He discusses the misuse of tuberculin from the time of Koch when Virchow's "myth" assailed it and he believes it is the physicians who are at fault. The technique of administering is fully given with charts. The book justifies and lauds Koch and favors the use of tuberculin as it has probably never before been favored.

BACTERIOLOGICAL DISEASES OF RESPIRATION AND VACCINES IN THEIR TREATMENT. By R. W. ALLEN, M.D., B.S., late Editor *Journal of Vaccine Therapy;* late Clinical Pathologist to Mt. Vernon Hospital for Diseases of the Chest, etc. Price $3.00. Philadelphia: P. Blakiston's Son & Co., 1913.

THIS book is quite a new departure in some ways. The author begins with a discussion of the bacteriology of the respiratory tract in health and disease—the bacteria found and the methods of collecting and examining them. He describes vaccine therapy as an artificial stimulant of the defenses against bacterial invasion and gives favorable reports of many sera and vaccines in such diseases as postnasal catarrh, bronchitis, asthma, pneumonia, and tuberculosis. To collect these diseases under such a heading is quite a new idea and the book shows careful study along these lines.

MALARIA—CAUSE AND CONTROL. By WILLIAM B. HORMES, M.A. Assistant Professor Applied Parasitology, University of California; Officer in charge Malaria Investigations, California State Board of Health. Price $1.50. New York: The Macmillan Co., 1913.

THIS book is dependent upon four years' study of malaria in California, and malaria is discussed from an economic as well as a medical standpoint. Malaria is not fatal, but expensive and the anopheles mosquito must be exterminated, to make life on the farm in California worth living. The mosquito was discovered as the cause in India in 1898 and is usually found in warm localities of low altitude. The life history of the parasite is described, especially the anophiline variety, and good illustrations are given. The essentials of control *e.g.* drainage, oiling pools, etc., are laid down and the author believes that the influx of colonists would more than offset the expense of extermination.

ÉTUDES D'ENDOCRINOLOGIE. By Dr. NAAME. Paris: A. Maloine, 1913.

ACCORDING to Dr. Naame glandular therapy has a very large field still untried. He reports cures of extreme cases of Asiatic cholera by the use of adrenalin. He also cures the sweats of tuberculous patients in the same way. In hysteria he gives parathyroid extract; also in epilepsy. The idea of ovarian extract in vomiting of pregnancy seems more in accordance with what we already know. His work is not based on laboratory experiments, but, as he says, upon "raisonnement expérimental," and needs further proof.

LE POST PARTUM NORMAL. By Prof. CONSTANTIN DANIEL (Bucharest). Paris: A. Maloine, 1912.

THIS book represents the results of the study of five thousand parturients. The author divides postpartum into three stages of one day, eight days, and five weeks respectively, and gives the symptoms and anatomical changes of all three.

DISEASES OF THE THROAT, NOSE, AND EAR. By W. G. POTTER, M.B., B.S.C., F.R.C.S., Edinburgh; Surgeon to Eye, Ear, and Throat Infirmary, Edinburgh; Surgeon to Ear and Throat Department Royal Hospital for Sick Children, Edinburgh; Aurist to Edinburgh Royal Institute for Education of Deaf and Dumb. Price $2.50. New York: William Wood & Company, 1913.

THIS is a book for the practitioner and senior student and deals with diagnosis and treatment as far as possible for the non-specialist. The illustrations are excellent and very clear. Diseases of the pharynx are discussed—acute and chronic inflammations and chronic infections (syphilis, tuberculosis). Diseases of the tonsils follow this, including diagnosis of chronic lacunar tonsillitis, etc. The methods of examining the larynx are next given, together with the diseases—acute and chronic inflammations, tumors, neuroses, etc. Under neuroses are descriptions of superior laryngeal paralysis, laryngeal spasm, phonasthenia, recurrent paralysis, etc. Rhinoscopy, with methods of examination, is clearly set forth, including transillumination and skiagraphy. Diseases of the nose and nasopharynx follow; also diseases of the accessory sinuses, with their semiology diagnosis and treatment. In the chapters on ear, examination is given both functional and otiscopic. Chronic suppuration is discussed at length with its complications. While the book does not describe any major operations it gives sufficient indication for these and describes the less complicated diseases so as to familiarize the uninitiated with them.

FOODS—NUTRITION AND DIGESTION. By SUSANNA COCROFT. Author of "Growth in Silence." "Self-Sufficiency," etc. First Edition, 1906. Second Edition, 1912. Chicago: Physical Culture Extension Society, 1913.

FOODS, by which is meant assimilable nourishment to form heat and energy, are classified into the old hackneyed groups. Water drinking at meals is found from 7,000 cases to increase flesh. Digestion is discussed, salivary, gastric, and intestinal, and the food value of different articles is discussed. There is a chapter on cooking; also diets are written out for different diseases. This latter list might be of use to the physician; the other chapters would probably interest housekeepers. The book is written by a lay person and has little, if any, scientific value.

Pathology. A Manual for Teachers and Students. By W. T. Councilman, M.D., Shattuck Professor of Pathology, Harvard Medical School. Boston: W. M. Leonard, 1912.

Professor Councilman has here written a textbook of pathology on an entirely new plan. While most similar manuals have also come from the hands of teachers, never before, we believe, has the planning and execution of a text been so subordinated to the object of producing a thoroughly efficient pedagogic implement. Its underlying thought is the conception, recognized by all instructors but only rarely carried out with logical completeness, that those things are most satisfactorily learned which the student acquires largely by the exercise of his own powers of observation and reason. Accordingly, it is the function of the teacher and also of the textbook so to guide the learner's efforts that he may not through his inexperience be led aside from the truth, or be caused unnecessarily to waste time in his progress from one step to the next while at the same time he is encouraged to make most of his advances on his own account. The present volume is most admirably adapted to serve in just this capacity for instead of being a mere catalogue of facts it comprises a complete scheme of laboratory work with the needful explanations and suggestions for enabling the student to make observations and deductions that will end by his building up a treatise on pathology of his own. For this purpose many blank pages are left on which the student is to make his records and his drawings, for none of the latter are supplied in the book, so that the volume in a sense is not complete until the intentional gaps have been filled in by its user. The plan is a difficult one to carry out consistently, and only an instructor of the author's experience and judgment could hope to vitalize such a skeleton of the subject sufficiently to give it flesh and blood outside the classroom. This Professor Councilman has succeeded in doing, however, and though of course the book is intended chiefly for undergraduates readers of all classes will find it of interest and value.

Die Behandlung der Krankheiten der Behaarten Kopfhaut. By Herxheimer and K. Altmann. Frankfurt a. M. 52 pages. Price 1.50 M. Halle a. S.: Carl Marhold, 1912.

The authors have considered only those diseases of the scalp which are worthy of special notice and which are amenable to treatment. Among these are: 1, chronic eczema; 2. hypertrophic processes, as ichthyosis, scleroderma; 3, neuroses, as pruritus zoster; 4. acute infectious diseases, erysipelas; 5, phlegmonous inflammations; 6, chronic infectious diseases, as syphilis, tuberculosis; 7, infectious diseases in which the organism is not yet known, as sycosis; 8, tumors.

Human Physiology. By Professor Luigi Luciani, Director of the Physiological Institute of the Royal University of Rome. Translated by Frances A. Welby. Edited by Dr. M. Camis, Institute of Physiology, University of Pisa. With a Preface by J. N. Langley, F.R.S., Professor of Physiology in the University of Cambridge. In Four Volumes. Vol. 1. Circulation and Respiration. Vol. 2. Internal Secretion, Digestion, Excretion. Skin, price per volume, $5.25 net. London: Macmillan & Co., Limited. New York: The Macmillan Company. 1911 and 1913.

Luciani has long held a great and deserved reputation as a physiologist and as a remarkably lucid writer. A sample of his powers of descriptive writing is given in the chapters on living matter, the first three of the first volume. The chapters on the blood are very readable, comprehensive and concise. The author allots the honor of discovering the circulation of the blood to his compatriot Cesalpinus. He refers to Harvey indeed, but only as a genius who wrote a little book of 700 pages which came out in Frankfurt in 1628 and which was unmistakably the masterpiece of a genius. Prof. Langley, alluding to this in his introduction, says: "It will be a shock to many English readers to find that Prof. Luciani allots the discovery of the systemic circulation of the blood to his countryman Cesalpinus. That the circulation of the blood was described and demonstrated by Harvey no one doubts. That there were a number of forerunners of Harvey who understood this or that important fact connected with the circulation is equally undoubted." No less than forty years ago Prof. Luciani revived the theory of "diastolic activity," which theory Stefani has placed on a firm experimental basis. The professor is therefore an authority on the mechanics of the heart and cardiac physiology. Nevertheless, so much has been found out by the investigations of Mackenzie and others that in many respects knowledge concerning the heart has undergone revision. Sixty pages are given to cardiac muscle and nerves, a subject on which the author is eminently fitted to speak. He deals with this matter in great detail. Thirty pages devoted to the vascular muscles and nerves complete the story of the circulation. The chemistry and physics of respiratory exchanges are clearly considered, together with an historical account of the same. Luciani himself, as is usually the custom of European medical writers, does not refer, except in rare instances, to the result of the researches of English-speaking scientific men. This omission, however, is, to some extent, rectified by the editor, Dr. Camis, who adds to each chapter the modern literature of the subject, of which the English part is somewhat scrappy. In the chapter on respiration no mention is made of most important work by Haldane, Hill and others.

The second volume is concerned with internal secretion, digestion, excretion and the skin and, of course, like the first volume, is beautifully written. Some of the subject matter, in the light of the revolution which has taken and is taking place in the views of scientific medical men with regard to the functions of the internal secretions, is scarcely up to date. It is a matter for wonder that the work of the veteran professor of physiology, one of the early Italian pupils of Ludwig, has not been translated into English before. It is a model of style and lucidity, and if the term fascinating is applicable to a medical book it is applicable to Luciani's work. It will serve, too, to introduce to American and English readers, not only his own work but much of the work done by his compatriots, of which but little is known. Than Luciani no one has, perhaps, a more comprehensive all-round knowledge of physiology. Miss Welby has acted as an efficient translator. It is to be hoped that there will be less delay in bringing out the future volumes. The first volume was published in 1911 and the second volume has been issued but a short time. The books are well bound, well illustrated and well printed.

Who's Who in Science. International 1913. Edited by H. H. Stephenson. London: I. & A. Churchill, 1913.

This issue of Who's Who in Science is an improvement upon its forerunner in that greater discrimination in the selection of names has been exhibited and it is not, as in the former edition, more British by far than international. A new Section on Scientific Societies and their publications has been added. Other new features are the recommendation forms and the frontispiece, consisting of portraits of eminent scientists who have died during the preceding year. There is yet room for improvement in the selection of names, the sins of omission are more obvious in this respect than the sins of commission. The book is well printed and bound and fulfills in a fairly satisfactory way the object for which it was written.

Conférence sur les Accidents du Travail et les Affections Traumatiques. By Dr. Olivier Lenoir, former interne of Paris Hospitals, laureate of surgical society, etc. Price 3.50 Fr. Paris: Vigot Frères, 1913.

This book has to do with forensic medicine though the choice of diseases discussed seems most peculiar in this connection. The author first speaks of the medicolegal aspect of tuberculosis and shows experiments to prove that this disease may be aggravated or localized by industrial injury but never caused by it. In syphilis, which he next takes up, he states that where innoculation occurs by industrial accident the patron is held responsible. Cancer is the third and last disease discussed. Full statistics and references of jurisprudence are given. The book will be of value chiefly to those concerned with the medicolegal aspects of the subject.

Die Chirurgie der Blutgefässe und des Herzens. By Dr. Ernest Jeger. Price 9 M. Berlin: August Hirschwold, 1913.

This book is based upon a thorough up-to-date study of the literature including much of Carrel's work, as well as personal observation. The illustrations are numerous and good. Technique for the different anastomoses, as well as intrathoracic work, is given. Also the results of these and of arterial transplantation. The changes of circulation following different anastomoses, such as the vena cava, with the portal vein, the splenic vein with the renal artery, the pulmonary artery with the aorta are described. Then follows a chapter on transplantation, *e.g.* kidneys, ovaries, heart and lungs, etc. The uses in human surgery of these experiments are given, for example, aneurysms, varices, transfusion, etc. The endothoracic aortic surgery, also the surgery of the pericardium and the technique of heart surgery are given. The book is excellent in many respects.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Sixty-Fourth Annual Meeting, Held at Minneapolis, Minn., June 16, 17, 18, 18, and 20, 1913.

(Special Report to the Medical Record.)

(Concluded from Vol. 83, page 1195.)

SECTION ON SURGERY.

DR. A. F. JONAS OF OMAHA IN THE CHAIR

Tuesday, June 17—First Day.

Chairman's Address: The Surgeon and the Research Laboratory.—Dr. A. F. Jonas of Omaha read this paper, in which he made the plea for a closer relationship between the operating surgeon and the research laboratory. The art of the practice of surgery was more than an art. It was to aim toward being a science, which was possible only by the application of the results obtained in the research laboratory. Clinical and bedside findings were more important than those of the laboratory, but were not sufficient. Ideal surgical institutions should have laboratories in connection with the operating rooms for the immediate study of specimens, and experimental work must be carried on close at hand. These departments must be in cooperation, otherwise proper applications were not made. The blood pressure apparatus was used 50 years in the laboratory before clinical use was made of it. In closing, the speaker urged particularly the study of the cancer problem.

Posterior Gastroenterostomy in Acute Perforated Ulcer of the Duodenum.—Dr. John B. Deaver of Philadelphia read this paper, which was based on his personal experience in over thirty cases. He emphasized the following points: Death was certain without operation; cure was certain with early operation. The diagnosis was based on the picture of acute indigestion, so called, with the sudden onset of violent agonizing, unbearable pain, abdominal rigidity, and the history of indigestion. Patients must be operated within first 24 hours; after 24 hours nearly all died. Of 26 cases operated on by the speaker before the end of 24 hours after the onset of symptoms 25 recovered. The early peritonitis was chemical, later the peritonitis was bacterial. The speaker advocated the following procedures: (1) Infolding of the ulcer with the plication of the duodenum in order to throw it out of function. (2) posterior no-loop gastrojejunostomy; (3) pelvic drainage through suprapubic stab; (4) avoidance of irrigation: (5) the sitting position, enteroclysis, and nothing by mouth until peristalsis was resumed; (6) ice bags to the abdomen; (7) masterly inactivity in the after-treatment, and (7) the free use of the stomach tube.

Dr. Ochsner of Chicago, Dr. Coffey of Portland, and Dr. W. H. Mayo of Rochester all agreed with the reader, making the point, however, that the skilled surgeon alone should practise enterostomy and that the amateur, who frequently must operate in these cases in order to secure early interference, should alone close the perforation and institute drainage.

Postoperative Ileus.—Dr. Angus McLean of Detroit read this paper which was based upon a vast amount of experimental work performed upon the dog. Artificial obstructions were instituted at various places in the alimentary canal and the chemical analysis of removed contents was made. The speaker's conclusions were that death in ileus was not due to toxemia, but was due to the loss of bodily fluids. He therefore advised as treatment enteroclysis and intravenous impressions to make up for such deficiency.

Congenital Dislocation of the Knees with Report of Two Cases.—Dr. John W. Perkins of Kansas City read this paper and demonstrated photographs and skiagraphs. He advised the resection of the joints and the permanent use of properly formed false joints.

Proctoclysis: An Experimental and Clinical Study.—Dr. Hugh H. Trout of Roanoke, Va., gave the results of his experimentation with plain tap water and normal saline solution for enteroclysis. He found that tap water was preferable to the saline in that it possessed all of the virtues of the latter and none of its objectionable features, as rectal irritation and actual salt thirst.

Etiology and Significance of Membranes about the Cecum and Colon.—Dr. David Cheever of Boston read a paper based upon the study of embryos, infants, and adults. He had reached the conclusion that there are several varieties of membranes about the cecum and colon. Some were congenital, that was, they were embryonic in origin. Others were inflammatory, but all were rarely of clinical significance. He advised against surgical interference except in the rare instances of actual obstruction.

Wednesday, June 18—Second Day.

External Bone Clamp versus the Internal Bone Plate in Fractures of Long Bones.—Dr. Leonard Freeman of Denver read this paper, and pointed out the following advantages: The simplicity of its use with minimum disturbance of the tissues; ease of removal at any time, which might be accomplished without anesthesia; fewer cases of delay or non-union, and the great advantage of not burying a permanent foreign body in the tissues. He claimed that the reduction was just as perfect as with the internal bone plate. The clamp should preferably not be used too near the epiphyses in compound fractures, particularly when infection was anticipated. The clamp was by all means the method of choice, not alone not doing harm but the screws themselves proved avenues for drainage.

Dr. Murphy of Chicago in discussing the paper recommended the use of the external bone clamp, saying that the plate should never be used in cases of compound fracture.

Dr. McArthur of Chicago reported very satisfactory employment in 210 cases of open fracture of the worst character occurring during the building of the Panama Canal.

The Mechanism of the Production of Fractures.—Dr. Emmett Rixford of San Francisco read this paper in which the subject was presented from the standpoint of the teacher, great stress being laid upon the fact that the principles of the mechanism were most important to the proper understanding on the part of the student. Incomplete fractures in children in the majority of cases were fractures by buckling; they were improperly designated in this country "green-stick" fractures. The Germans more correctly call them subperiosteal fractures. Fractures of adult long bones usually resulted from tensile stress. Spiral fractures resulted from twist, and so occur always in the direction of the twist. Fractures of short bones resulted from the compressive or tensile stress.

Surgical Management of Injuries to the Elbow Joint, Primary and Secondary.—Dr. John B. Murphy of Chicago said the poor results obtained in the treatment of joint injuries were bringing more discredit to the profession than any other branch of the practice. The time was not distant when the profession would be held financially responsible for these avoidable evils. Poor results in the treatment of injuries of the elbow joint follow luxation, and fractures were next in frequency to those of Colles' and Pott's. By more careful and thorough diagnosis, an insistence upon perfect reduction and the maintenance of the same these results could be avoided. When perfect reduction could be obtained and maintained by conservative bloodless manipulation, operation and the nailing of fragments must be resorted to. Fractures of the external and internal condyle, or both, might be nailed with the ordinary eight, ten or twelve pennyweight carpenter nail through a small nick in the skin. This could be done with impunity, and great numbers of skiagraphs demonstrating practically perfect results were thrown on the screen. Fracture of the olecranon process was also held better by nailing than by the former method of subcutaneous wiring. The non-union of fractures had become a very common condition; ten times more common since the year 1895 than previous to that time. Dr. Murphy believed that this was due to the too perfect and rigid holding together of fragments, as by the bone plate and plaster cast. Slight motion and irritation to the ends of fragments favored osteogenesis. Lane distinctly advised against the use of the bone plate in cases of non-union for this same reason. The Germans in applying plaster casts always had the patient walk about so as to obtain this desired stimulation by irritation of bone production. Volkmann's paralysis was a traumatic myositis followed by degeneration atrophy of the muscle fibres due to too tight bandaging and always occurred within the first 48 hours. He absolutely deprecated the practice of passive motion. Passive motion caused irritation, laceration, increased hæmorrhage, and so increased osteogenesis, resulting in the over-production of callus formation with the subsequent limitation to the function of the joint up to and including the degree of ankylosis. Very useful joints could be made of these ankylosed conditions by resections or the formation of artificial non-union above the elbow joint.

Drs. Cotton of Boston, Lemon of Milwaukee, Sherman of San Francisco and Willy Meyer of New York discussed the paper, all of whom agreed with Dr. Murphy in

urging less passive motion in the after-treatment of fractures in the neighborhood of joints. They all, however, believe that the conservative non-operative methods were sufficient in the great majority of cases, and operation should be the last resort.

Surgery of the Thyroid.—Dr. CHARLES H. MAYO of Rochester read this paper. His conclusions were based on the observation of 5000 operations. Drinking water seemed to have much to do in the etiology of thyroid disease. Transplantation of the gland in cases of defective thyroid was of no more value than the feeding of such gland, as it was in a short time eaten by the host. The vocal chords and all enlargement of the glands should be examined, as paralysis of one of the chords from pressure frequently occurred without alteration of the voice, due to the pressure of the recurrent laryngeal nerve, the left being more commonly involved. Substernal thyroid was more common than was generally appreciated and should be regularly examined for. Diagnosis was made by dullness on percussion over the sternum and by *x*-ray examination. Iodine was of benefit in the simple hyperemic goitre. It was of real danger when given to cases of fetal adenoma or old colloid goitre, in which, due to the stimulation a state of thyrotoxicosis developed, the latter condition in a short time giving myocarditis. *X*-ray treatment was of value at times in carrying a patient over an acute exacerbation of the exophthalmic type. The operation of litigation was very important in severe cases as a preliminary step in the preparation of the patient for the more radical procedure. Partial thyroidectomy cured the progression of the thyrotoxicosis but the injury already caused to the nervous system, heart, etc., was permanent. Removal of the superior and middle sympathetic ganglia frequently cured the exophthalmia.

Dr. OCHSNER in the discussion of the paper told of a village in Switzerland in which 70 per cent of the inhabitants were afflicted with goitre. A change in the water supply very greatly reduced the development of thyroid in young individuals. He advocated the boiling of water in thyroid districts.

Study of the Circulation in Some Cases of Gangrene of the Feet.—J. E. THOMPSON of Galveston said that from the very careful study of three cases of gangrene, one of thrombosis and two of diabetes, and review of the literature, the author concluded that amputation through the lower third of the thigh was invariably the proper site. Even with the main trunks completely blocked the collaterals would be sufficient to nourish the flaps in this location.

Extrathoracic and Intrathoracic Esophagoplasty.—Dr. WILLY MEYER of New York read this paper. The author urged complete radical extirpation of all malignancy of the esophagus, removing the malignancy wide and providing for the replacement of the function of the esophagus later. A tube outside of the thorax would enable the patient to swallow as well as inside, or plastic formations of new tubes by employment of skin or even transposed coil of small intestine has been successfully employed. The rubber tube connection employed outside of the thorax between the stomach opening and the oral opening was very satisfactory. Cancer of the lower third of the esophagus in the light of recent animal experiments would probably before long be likewise radically dealt with.

Oration on Surgery: Who Shall Do the Surgery?—Dr. WILLIAM D. HAGGARD of Nashville, in this address said: Modern surgery has made such great advances and become such a large subject that special preparation is required for its practice. The profession must insist upon better trained men, otherwise great discredit will result therefrom. Of 4500 graduates there are 3000 internes, which is not enough, and the writer recommended that all medical schools should require the fifth hospital year. He urged the establishment of special courses for the training of surgeons, and then a special degree as of M.S.—Master of Surgery—be given to those qualifying themselves. This work should consist particularly of the study of gross pathology, surgical anatomy, operative surgery on the cadaver and animals, and research laboratory work done in connection with clinical work at hospitals. Following this, an apprenticeship of from three to five years with an established surgeon was recommended

Chronic Focal Infections as a Causative Factor in Chronic Arthritis.—Dr. FRANK BILLINGS of Chicago presented this communication. As a result of work experimental and clinical performed in close co-operation by medical, nose and throat, laboratory and surgical practitioners a great deal of information regarding chronic arthritis and myositis and neuritis was obtained. His conclusions are that they are practically all due to chronic focal infections. Focal infections of the tonsils, of the sinuses of the head, of the dental alveoli, of the prostate, of the seminal vesicles and of the urethra, gall bladder, appendix, and elsewhere are causative. The treatment is removal of the cause. Gratifying results have been obtained by autogenous vaccines.

Infections of the Prostate and Seminal Vesicles: Their Rôle in Toxemia.—Dr. HUGH YOUNG of Baltimore said that prostatitis and vesiculitis were very commonly involved in gonorrheal urethritis without symptoms, manifesting themselves in later life by rheumatic infections. Prostatitis was frequently caused by infections from the rectum, more commonly in cases of hemorrhoids. These lesions frequently caused lumbago, sciatica, multiple arthritis, bursitis, myocarditis, and nervous symptoms, all of which had been cured by attention to the cause. For prostatitis and vesiculitis the treatment was massage, prostatectomy, or incision of the seminal vesicles.

Injection of Boiling Water for Hyperthyroidism.—Dr. MILES F. PORTER of Fort Wayne, Ind., read this paper. From a clinical observation of over twenty cases the author recommended the employment of the treatment in very severe and mild cases of hyperthyroidism. The immediate effect of the injection of the boiling water was the actual destruction of the thyroid cell in the vicinity of the injection and thus diminution in the quanitty of tissue forming the secretion.

Thursday, June 19—Third Day.

Nephritis as a Surgical Problem, and Its Treatment as a Preliminary to Operation.—Dr. J. F. PERCY of Galesburg, Ill., in this paper, advocated the use of desiccated thyroid gland in large doses as a means of improving the surgical risk in cases of nephritis. He reported some cases of actual cure of the condition. The treatment is contraindicated in cases complicated by incompensation of the heart, in severe chronic myocarditis, and in inflammations of the kidney secondary to infections of the genito-urinary tract. The thyroid extract may be of value as an agent in cases of suppression of the urine.

Technique of Röntgenoscopy of the Gastrointestinal Tract, and Interpretation of Screen and Plate Findings.—Dr R. D. CARMAN of Rochester, Minn., from the observation of a large number of cases advised more routine *x*-ray examination, many unsuspected lesions being found by so doing.

The Added Responsibility of the Surgeon when Called On to Treat Surgical Lesions in Their Earliest Stages.—Dr J. C. BLOODGOOD of Baltimore made a plea for greater attention and more thorough examination of patients with mild symptoms. A failure to diagnose malignancy in its incipiency is a much greater mistake than later in the disease, for in the early stage the condition is curable by operation, and in later never. The real problem of surgery today is the one of making early diagnosis, and particularly in cases of malignancy.

Fetal Peritoneal Folds and Their Relation to Postnatal Acute and Chronic Occlusions of the Large and Small Intestines.—Dr. J. RILUS EASTMAN of Indianapolis cited cases of acute obstruction of the colon due to Jonnesco's parietocolic fold, or Jackson's membrane. Acute obstruction has been caused at various places in the alimentary canal by these membranes. Many of the cases of intestinal stasis, chronic autointoxication, are frequently caused by the persistence of these fetal membranes and folds.

Symptoms and Diagnosis of Membranous Pericolitis.—Dr JABEZ N. JACKSON of Kansas City, Mo., read this paper. He said that pain along the course of the ascending colon, general diffuse tenderness over the whole abdomen, constipation, mucous colitis, tympanitis, digestive disturbances, neurasthenia, all resulting in loss of weight, were the main symptoms in the diagnosis of membranous pericolitis. Roentgenoscopy was of great value in demonstrating the stasis and sites of obstruction. Temperature and pulse disturbances were always absent.

The Necessity of Preserving the Periosteum in Bone Transplantation.—Dr. CLARENCE A. MCWILLIAMS of New York read a paper based upon a vast amount of experimental work in bone transplantation. The author concluded that the life of the bone graft depended exclusively upon its blood supply, the periosteum or marrow present or absent having no particular effect. Small fragments of bone denuded of their periosteum would live in tissues without absorption, due to rich blood supply. Large fragments without periosteum died because of insufficient blood supply. The periosteum was bone forming and lived when

the bone died because of its ability to appropriate nutrition. Complete subperiosteal bone resection was followed by the reforming of the bone.

Röntgenoscopy of the Liver and Biliary Passages.—Dr. JAMES T. CASE of Battle Creek, Mich., has found the *x*-ray examination of the liver to be of value in diagnosing changes in the size and shape of the liver, local tumors, hepatic and subphrenic abscesses, adhesions, and in many cases of gallstones giving vague symptoms.

Original Uses of the Bone Graft in Surgery.—Dr. FRED H. ALBEE of New York reported the results of his use of bone graft in the treatment of fractures of the spine, all long bones, neck of the femur, and club foot, showing a large number of skiagraphs and pictures as proof. His results had been very satisfactory and the paper was well received. Dr. Albee uses graft with periosteum and bone marrow, believing the latter two conditions, though not always essential, to be of value in insuring future life of the graft.

Symposium on Anesthesia.—Dr. HARRY G. SLOAN of Cleveland, in his paper on nitrous oxide and oxygen anesthesia claimed that it was particularly indicated in very bad surgical risks, they taking it the easiest. It was the anesthetic de luxe; it was pleasant to take and causes less post-anesthesia nausea. Diabetics did well with the anesthetic. Due to the inability to obtain complete relaxation as with ether local blocking of the nerves was resorted to. The principal disadvantages were the cost of the apparatus, the necessity of a skilled anesthetist, and the difficulty of obtaining pure gas.

Dr. CHAS. H. PECK of New York gave a report of very satisfactory employment of the intratracheal insufflation anesthesia in 334 of his personal cases of all varieties.

Dr. J. F. MITCHELL of Washington, D. C., referred to the extensive use of local anesthesia in Europe and predicted its greater employment by American surgeons. It was particularly indicated in operative work in the aged, and whenever general anesthesia was contraindicated. By the intravenous method of Bier all major surgery of the extremities might be performed, the particular value of its employment being the protection of the center nerve system from shock due to the blocked condition of the nerves. Practically all surface surgery of the torso, and all of the major surgery of the extremities might be performed under local anesthesia.

Surgical Aspects of Intestinal Stasis from an Anatomical Point of View.—Dr. JOHN E. SUMMERS of read this paper. Mechanical obstruction and interference was responsible for a large number of cases of intestinal stasis. Neglect of the function, and disease of the nervous system also played a part and frequently result secondary to the mechanical condition, forming a vicious circle. The recent interest in these various constricting membranes had been occasioned by the writings of Lane and Jackson, who were, however, only redescribing conditions observed and recorded by Jonnesco and Juvara, Treves, Reid, and others. These were mostly due to embryonic conditions. Some were of inflammatory origin and gave rise to the conditions of obstruction and intestinal stasis, which could alone be relieved by operative interference.

Friday, June 20—Fourth Day.

Gastric Tetany.—Dr. W. L. RODMAN of Philadelphia claimed great satisfaction in the treatment of gastric tetetany by gastroenterostomy or pyloroplasty. The relief obtained was usually very prompt. The indication in the treatment is that of gastric drainage. Gastric lavage continued for long periods of time may carry a patient along, and now and then result in a cure. Sedatives such as morphine, bromids and chloral are indicated.

An Experimental Study of the Mobilization of Ankylosed Joints.—Drs. NATHAN ALLISON and BARNEY BROOKS of St. Louis read this paper. The following conclusions were arrived at as a result of the review of the literature and personally conducted experiments and clinical work. Mobilization of ankylosed joints was based upon the freeing of such ankylosis, and the interposing of materials to prevent a return of the ankylosis: Cargile membrane, Baer membrane, silver nitrate fascia, fascia with a pedicle, free fascia and killed fascia. Among these the interposition of fascia had yielded the most satisfactory results.

Therapeutic Possibilities of Transfusion.—Dr. BERTRAM M. BERNHEIM of Baltimore said transfusion of blood was indicated in cases of exsanguination, in toxemias, and many of the blood conditions as splenic and pernicious anemias. It should be performed in earlier stages of these conditions to ascertain its real value, as the method gives promise of great value. The method was harmless, and the difficulty in the past had been that it had been performed usually only upon moribund patients, and even then with marked degrees of success.

Theory and Practice of Transfusion.—Dr. J. J. HOGAN of San Francisco concluded as a result of experiments to ascertain the comparative values of solution for transfusion that the beneficial effects from the salines while very marked is very transitory. Human blood serum is of much more permanent value, and whole blood the superior of all.

Thyroglossal Cysts and Fistulæ: Report of Three Cases.—Dr. HERMANN B. GESSNER of New Orleans read this paper. Thyroglossal cysts and fistulæ were of embryonic origin, being remnants of the ducts leading from the foramen cecum to the isthmus of the thyroid. The fistulæ always opened in the median line of the neck in contradistinction to those resulting from permanency of branchial cleft structures. The skiagrams of injected fistulae were of great diagnostic and operative value. The treatment was by excision.

SECTION ON MEDICINE.

Wednesday, June 18—Second Day.

The Clinical and Pathological Relationship of Hyperplastic and Nonhyperplastic Goiter.—Dr. H. S. PLUMMER of Rochester, Minn., presented this paper in which he stated that clinically cases of goiter might be classified into simple or exophthalmic, or equivalent terms, and the pathological classification of thyroids removed at operation into those with and those without sufficient hyperplastic or hypertrophic changes to characterize the gland; hyperplastic changes were found in from 70 to 90 per cent. of the thyroids removed for exophthalmic goiter. In the main the length and severity of the case history could be pointed out from the pathological findings. Toxic goiter heart was recognized in a certain proportion of cases not diagnosed exophthalmic goiter. A review of the clinical histories and pathological reports of their entire series in the latter part of 1908 led the author to the following conclusions: 1. There were at least two distinct types of thyroid intoxication, one associated with non-hyperplastic goiter, the other associated with hyperplastic or hypertrophied thyroids. 2. All cases having thyrotoxic symptoms with notable hyperplastic thyroids should be diagnosed exophthalmic goiter and that cases having thyrotoxic symptoms, without notable hyperplastic thyroids, should be classified with the toxic goiter heart. The main objection to these conclusions was the difficulty of making the clinical and pathological diagnosis agree in about 10 per cent. of the cases. He had attempted to answer the questions brought up with the least possible amount of data, using the following factors: the age at which the goiter was first noticed by the patient; the age at which thyrotoxic symptoms developed; the presence or absence of exophthalmos; the presence or absence of notable hyperplasia in the thyroid. The term thyrotoxicosis was applied to the constitutional state associated with goiter. The cases had been classified pathologically as hyperplastic and non-hyperplastic, and clinically as hyperplastic toxic and hyperplastic atoxic, non-hyperplastic toxic and non-hyperplastic atoxic. Following this classification for the new cases, 2,917 coming to operation between January 1, 1909 and January 1, 1913, 42.8 per cent. were hyperplastic and 57.2 per cent. were non-hyperplastic. Of those which were hyperplastic 99.2 per cent. were toxic and 0.8 were atoxic. Of the non-hyperplastics 23.3 per cent. were toxic and 76.7 per cent. were atoxic. Patients coming under observation with non-hyperplastic toxic goiter gave a history of having first noticed the goiter at the average age of 22 years, and the evidence of intoxication at the age of 36.5 years. The corresponding ages for hyperplastic goiter were respectively 32 and 32.5 years. That non-hyperplastic goiter was noted ten years earlier in life than hyperplastic goiter, that 14.5 years elapsed between the appearance of non-hyperplastic goiter and the development of notable toxic symptoms, and that the constitutional symptoms were noted but a few months later; that the goiter in the patients affected with hyperplastic thyroid was alone sufficient to show that they were dealing with at least two distinct pathological and clinical groups. That one was not the sequence of the other was self-evident. The majority of hyperplastic goiters coming to operation had moderate toxic symptoms indicating that the activity of the thyroid was proportionate to the degree of hyperplasia. Though there was much evidence on the affirmative side one could not definitely state at the present time that hyperplasia of the thyroid was more prevalent in the first two decades of life than they had definite knowledge of, neither could it be affirmed definitely that this hyperplasia of the thyroid

could be sharply distinguished from the hyperplasia associated with Graves' disease which developed at the average age of 32. As to whether the exophthalmos of thyrotoxicosis was always associated with hyperplastic goiter, the pathologists' reports failed to show the presence of hyperplasia in the cases in which exophthalmos was noted by the clinician six times in 1909, four times in 1910, two times in 1911, and not a single instance in 1912. In 1912, 911 new cases of goiter came to operation. In most of the exceptions to the rule previous to 1912, they had been able to prove that there was an error on noting the presence of exophthalmos. It was quite possible that exophthalmos might be associated with non-hyperplastic toxic goiter, but, if so, it was so rare that it must be in a way considered accidental. As a matter of convenience in this paper he had considered the symptom complex accompanying hyperplastic goiter and directly attributable to disturbed thyroid function, and while he did not wish to discuss this subject at the present time he called attention to a point in support of this theory, that so far as he knew had not hitherto been made, namely, that an individual 22 years of age, with an adenoma of the thyroid, had a definite chance of developing a train of symptoms during the thirty-sixth year so similar to the symptoms complex associated with hyperplastic thyroid that the best trained diagnosticians were constantly confusing the two conditions. The author thought that at present they could not associate the symptom complex of non-hyperplastic toxic goiter with any definite pathological change in the thyroid.

Diseases of Porto Rico.—Dr. ELMER F. OTIS of Penuelas, Porto Rico, read this paper. He stated that there were only two or three diseases strictly limited to the tropics, and if they considered all the diseases that occurred in the tropics they would have to cover the entire field of medicine. They had the arthritides and rheumatism even in warm climates. Tuberculosis presented a more puzzling problem in the tropics than in the temperate zones. This disease had increased with the increase of population and crowding, and was fostered by the prejudice of the people against ventilation. Typhoid fever was endemic in the island and malaria presented some uncommon phases; it was much more malignant than in the north. Eye affections, especially cataracts, were frequent, particularly in those affected with the hookworm. Intestinal obstruction was common owing to the irregular habits of the natives. There were thirty cases of leprosy on the island, but yellow fever no longer visited them. The plague had visited them in 1912 but was controlled by the sanitary department of the island and the United States War Department, and that without obstructing commerce It was evident that through the enforcement of sanitary regulations they could cope with disease as effectively in the tropics as elsewhere.

Study of a Case of Congenital Hemolytic Jaundice.—Dr. ERNEST T. F. RICHARDS of St. Paul, Minn., reported this case, and gave a very accurate description of the condition of the blood in these subjects. The only rational treatment seemed to be iron unless one wished to resort to splenectomy. He illustrated the blood picture with lantern slides, showing the diminished osmotic resistance of the erythrocytes and the point higher than normal at which the patient's corpuscles showed slight hemolysis. He also illustrated the marked decrease in the size of the erythrocytes and the anisocytosis in congenital hemolytic jaundice.

Dr. WILLIAM S. THAYER of Baltimore reported a case that had come to him a year or two ago. The girl had always been jaundiced. The spleen was enlarged a hand's breadth below the costal margin. As the jaundice in this case was slight and as the symptoms were so light in his patient he did not think that the condition called for splenectomy. The congential type needed little treatment except for the cosmetic effect but acquired cases might be instances of pernicious anemia.

Dr. JOSEPH L. MILLER of Chicago said that a case under his observation at the present time showed that the blood hemolyzed at about normal. When a patient had chronic icterus the blood had a marked difference in resistance of red blood corpuscles in this form.

Federal Control Over the Manufacture of Serums and Vaccines.—Dr. JOHN F. ANDERSON, Director Hygienic Laboratory, U. S. Public Health Service, Washington, D. C., read this paper, which gave an account of the way in which the United States Government safeguarded the manufacture of important products, such as diphtheria antitoxin, tetanus antitoxin, vaccine virus and other similar preparations. He showed that the manufacture and sale of these products was under the strictest kind of supervision and that the least deviation by the manufacturer from the established methods in the preparation of these products was at once checked by the Government. Before the U. S. Public Health Service was given authority by Congress, in 1902, to exercise this supervision the manufacturers were under no control as to potency or purity of their product, being guided solely by the commercial considerations involved in putting out a better preparation than their competitors; but since the enactment of this law giving authority to the Public Health Service to supervise the manufacture of these important preparations every safeguard has been thrown around them, and physicians in the United States using a package of diphtheria or tetanus antitoxin could now be assured that the patients would receive the full therapeutic effect of the contents as stated upon the label. The enforcement of this act had been of inestimable value in the safeguarding of biological products.

Treatment of Pneumonia by Specific Serums.—Dr. RUFUS I. COLE of New York read this paper. He stated that pneumococci might be divided into several groups, each with specific biologic characters. An immune serum which was active against members of one of these groups was not active against the member of other groups, and this explained why pneumococcus sera had so often proved of no value in particular cases of pneumonia. Therefore, in an attempt to treat pneumonia by specific serums it was necessary to determine first the specific group to which the infecting organism belonged. In determining to which group the pneumococcus in a given case belonged they examined cultures from the sputum, the blood, and sometimes from the lung. They had studied 74 cases of pneumonia which had fallen into four groups which they had designated as type I, type II, type III (pneumococcus mucosus) and type IV (heterogeneous organisms). Of the 74 cases 47 per cent. belonged to the first group, 18 per cent. to the second group, 13 per cent. to the third, and 22 per cent. to the fourth. They had had a mortality of 24 per cent. in the first group, or 61 per cent. in the second group, 60 per cent. in the third and 7 per cent. in the fourth. The mortality in the whole group was 32 per cent. When the culture was not agglutinated by serum of the first or second groups it was taken that the case belonged to the third or fourth group. Of 20 cases treated there were 13 of type I and three of type II. They had found serums that seemed to be active against the first two groups, but thus far no serum had seemed to have any effect on the third and fourth groups. In order to avoid anaphylaxis they gave a preliminary dose of four c.c. of the serum. All of the cases showed a marked reaction after the injection of the serum; some had chills and a rise in temperature and others had serum disease some day after the administration of the serum. It was not clear just how the serum acted, but there seemed to be a lessening in the degree of toxicity. The author also discussed the protective power of the serum when administered at different times during the progress of the disease and said that this protective power seemed to be greater the earlier the serum was given. He felt sure that further study in this field would be productive of definite results. He thought that part of the action of the so-called antibacterial serums might be antitoxic.

Antistreptococcic Serum.—Dr. GEORGE H. WEAVER of Chicago read this paper, in which he described how the antistreptococcic serum was produced and his theory of the mechanism of its action, and also how passive immunity was produced and the mechanism of its action, discussing the action of opsonins and antitoxins. A protective serum had little curative power in active infection. To secure the best results the serum should be brought in contact with the infecting organism as soon as possible and to effect this the intravenous method of administration gave the quickest method. Larger doses than were usually administered were required to produce an effect. Thirty to 100 c.c. when given subcutaneously gave results only after from twenty-four to forty-eight hours. When there was a fall in the opsonins after an earlier rise the dose was repeated. The author discussed the conditions and indications for the use of the serum. A bacteriological diagnosis furnished the only dependable basis as to whether the administration of the serum was indicated. There was, of course, no use in administering a streptococcus serum in case the infection was due to some other organism. Again one must be sure that the serum was active. The doses usually used had been too small—10 to 20 c.c.—while a dose of 50 to 100 c.c. was nearer the correct one.

The Treatment of Lobar Pneumonia with Partially Autolysed Pneumococci and Pneumococcus Extracts.—

Dr. E. C. Rosenow of Chicago read this paper. He said that he had been working for four years on the autolyzed products of pneumococci and pneumococcus extracts in the hope of finding some product of the pneumococci which would be useful in the treatment of pneumonia. Passive immunity had failed to give the protection necessary and it was necessary to have the pneumococci in a state of high virulence. From the work of Dr. Cole it now looked as though this might be possible. A highly virulent culture placed in salt solution had no particularly toxic effect after a certain period; at first a highly toxic substance was autolyzed, but if the autolyzation proceeded still further the toxicity was lost to such an extent that it could not be restored by any methods thus far employed successfully with other bacilli. When autolyzed pneumococci in twenty million doses were injected there was a prompt increase in opsonins. During the past two years they had used a combination of the partially autolyzed and the non-toxic serum and they had had better results. They had treated 150 cases during the past three years in the Cook County Hospital and had used 150 cases as controls. In 1911 the mortality among the treated cases was 32 per cent., while among the untreated control cases it was 48 per cent.; in 1912 the mortality among the treated cases was 23 per cent., while among the untreated it was 31 per cent.; in 1913 the mortality was 14 per cent. among the treated cases and 32 per cent. among the control cases. The cases were of the character usually received in such institutions, the mortality being far higher than in private practice. While Dr. Rosenow did not wish to be over-enthusiastic he said he believed that the detoxicized pneumococcus was a remedy that would do good in lobar pneumonia. In 75 per cent. of the cases treated last year he found that if the pneumococcus serum was given early the disease was cut short. If, however, consolidation was complete the temperature showed no definite change after the administration of the pneumococci. He had no explanation to offer which would explain the action of this preparation of pneumococci which was in accord with the present knowledge of immunity. If it proved useful they should use it and continue to search for the explanation. While he did not advocate practically autolyzed pneumococci as the remedy *par excellence* for pneumonia, he thought that its proper and early use was of real benefit.

Typhoid Vaccination in the Army.—Dr. Frederick F. Russell of Washington, D. C., read this paper and gave a lantern slide demonstration. He said that vaccination against typhoid was begun in March, 1909, on volunteers from the Medical Corps, Hospital Corps, and Army Nurse Corps. The first year 1,887 persons were vaccinated; in 1910, 16,073. In March, 1911, compulsory vaccination was ordered for troops on the Mexican border (20,000), and in June, for all recruits, numbering from 2,000 to 3,000 per month. In October it was ordered for all persons in the service under 45 years of age. The results were shown in the following table:

Year	Mean Strength	Absolute Cases	Number Deaths	To each 1,000 soldiers of the command, the ratios are:	
				For Cases	For Deaths
1901	26,515	250	17	9.43	.64
1902	39,736	341	34	8.58	.86
1903	42,264	246	12	5.82	.28
1904	43,940	247	12	5.62	.27
1905	42,834	133	13	3.57	.30
1906	40,621	230	12	5.66	.28
1907	35,132	124	7	3.53	.19
1908	46,316	136	11	2.94	.23
1909	57,124	173	16	3.03	.28
1910	55,680	129	9	2.32	.16
1911	55,240	44	6	0.80	.11
1912	58,119	15	2	0.26	.03

The vaccine was made from a carefully selected single strain of the bacillus typhosus grown on agar. The first dose was 50 million bacilli, the second and third, given 10 and 20 days later, 1,000 million. No ill effects had been reported. The last case of typhoid in the army occurred on December 9, 1912.

The same vaccine offered protection against the typhoid of all different localities. The statistics showed that vaccination against typhoid was as successful as that against smallpox. A preliminary vaccination did no harm if typhoid fever did develop. They did not know the duration of immunity conferred by vaccination and hence they vaccinated every four years because they aimed to get the maximum immunity. There was no evidence to show that it activated tuberculosis or any other chronic disease. At the present time they did not care to use a vaccine containing living bacilli, since they were sure that the vaccine now used produced no harmful results. Cases of paratyphoid fever were so rare that it was not advisable to double the dose of bacteria in order to reach them. In patients who had been vaccinated the diagnosis was made by a blood culture. The fact that the men were vaccinated did not lead them to slight any other sanitary measures.

Dr. Joseph L. Miller of Chicago, Ill., said that there was no study so full of difficulties as that of therapeutics, and especially in acute infections. The percentage of recoveries varied greatly in different epidemics, and there was a great variation in the degree of the intensity of the infection in different individuals. One must have a wide experience as to individual data and a suitable number of control cases if he would reach reliable conclusions. The papers read had been of unusual value in that they dealt with facts and not with impressions.

Dr. W. V. Brem of Los Angeles, Cal., related an instance in which he had used a streptolytic serum, together with a normal human serum in a case of streptococcic meningitis. He administered 100 c.c. subcutaneously, and although he obtained a negative spinal fluid so far as the streptococcus was concerned and there were none in the smears, yet the septicemia increased and the patient died. After hearing the papers he would now give a large intravenous injection in such a case. He said he wished to take advantage of this opportunity to speak of the doubtful laboratory products against which the government could not as yet protect them. Many were using the phylactogens; the reports in regard to the action and benefits of these products that were given them were from the proprietors; there were only two or three reports in medical literature. The reports in regard to such products should come from the prophets of the profession and not from the manufacturers.

Thursday, June 19—Third Day.

The Water-Trap Stomach: Symptomatology, Diagnosis and Treatment.—Drs. G. Reese Satterlee and L. T. LeWald of New York presented this communication and made the following deductions: (1) While the condition of water-trap deformity was observed in early youth the usual time these cases presented themselves for radical treatment was between the age of 30 and 40. (2) These patients had invariably suffered for years. With symptoms erroneously diagnosed as "neuralgia of the stomach," "ulcer of the stomach," "nervous indigestion," "neurasthenia," or "dyspepsia," the limit of endurance had only been reached after sixteen years of suffering. (3) Coloptosis, nearly always present, was not present in 16 or 100 cases. (4) "Residue" or food remaining an abnormal length of time in the stomach gave in 16 cases symptoms such as pain five or six hours after eating, most frequently at night in the early morning, and flatulence. Fifty per cent. of the 16 special cases had the symptoms and the residue was demonstrated by the *x*-ray. In the 100 cases 55 per cent. showed residue by means of the *x*-ray. This residue was caused by sluggish motoric functioning of the stomach. (5) The drag was evidenced by symptoms of a dragging sensation in the abdomen, flatulence and eructations. These symptoms were caused by the constant pull of the ptosed hollow viscera upon the visceral nerves and blood vessels. Symptoms were present in all of the 16 cases. This sensation of "drag" had been one of the most constant symptoms and one of the first to be relieved by proper treatment, whether medical or surgical. (6) There was loss of weight. This was present in 13 out of the 16 selected cases. In the cases that showed improvement after treatment, medical or surgical, there was a gain in weight of ten or more pounds. (7) Vomiting was not a prominent symptom, and was present in only four of the 16 cases studied in detail and in 35 out of the 100 cases. (8) Constipation was present in 13 out of the 16 cases, but in only 45 out of the 100 cases. It was undoubtedly a factor, but its exact relationship was not easy to determine. (9) In the 16 cases reported in detail only four were in multipara. Eighteen of the 100 cases were treated by abdominal section. In practically every case in which a thorough form of suspension technique was employed had up to date done well. The operation of choice was gastropexy and colopexy. Indications for Operation.—1. In those cases of water-trap stomach of a severe grade with a residue in the stomach after six hours and that had resisted medical treatment for a considerable length of time. 2. Those cases that showed a gradual steady loss of weight and strength under the

same conditions and treatment. 3. Those cases that could readily demonstrate that there was a constant discomfort from the condition after a reasonable amount of medical treatment. Contraindications.—The simple ptosed stomach and the simple dilated stomach. The rule in these cases was subjected to occasional modifications. Gastrocoloptosis in multipara with lax abdominal walls and with no evidences of the water-trap deformity. The medical treatment as outlined in the large majority of the cases consisted of (1) correcting the position and drag by (a) proper fitting abdominal supports; (b) elevating the foot of the bed to limit of tolerance; (c) turning the patient on the right side after meals, with the thighs elevated.

2. Attention to a digestible diet and hygiene, especially if constipation was present. These patients were not to be put to bed but kept on their feet. If rest was necessary the indications for operation should be carefully considered. The author drew the following conclusions: I. The water-trap stomach was a morphological entity, a "deformed organ" which gave rise to a certain definite train of symptoms. II. That its origin was probably largely embryological and developmental. III. The water-trap stomach should be distinguished from a simple gastroptosis. IV. It occurred mostly in women. V. Constipation, although it might not be an exciting cause, was present in over fifty per cent. of the cases. VI. This condition was very frequently wrongly diagnosed as an ulcer of the stomach or duodenum. VII. So far, its exact diagnosis did not seem feasible without the aid of the *x*-ray. VIII. In the mild grades medical treatment alone was necessary. IX. In the severe grades operation was often indicated, and in some of these was the only means of relief.

Gastroscopy, with Demonstration.—Dr. Henry H. Janeway of New York read this paper. He said that all admitted the need of gastroscopy, provided a satisfactory view of the interior of the stomach can be safely obtained thereby and without causing the patient to suffer. The demonstration accompanying the paper should satisfy the first of these conditions. The clearness of the views depend in a large part on the improved telescopes. With them it was possible to get a satisfactory view of the vertical portion of the stomach in the majority of cases. Fifteen carcinomas of the stomach had been diagnosed by this means by the writer. In the majority of these the diagnosis was confirmed by sections of a portion of a piece of tissue removed at the time of the examination. The intratracheal anesthesia, particularly by nitrooxide and oxygen, satisfied the second condition. There should be no excuse therefore, for the failure to include gastroscopy among the routine methods of gastric examination. Gastroscopy completed the radiographic examination of the stomach in the cardiac region where radiography found a smaller field in usefulness. In the same manner radiography complemented gastroscopy in the pyloric region of the stomach.

Points of Value to Be Derived from Röntgenoscopy of the Gastrointestinal Tract.—Dr. R. Walter Mills of St. Louis, Mo., presented this paper. After pointing out the deficiency of the ordinary methods of auscultation and palpation in determining the topography and conditions of the gastrointestinal tract he pointed out the advantages of the *x*-ray in the diagnosis of obstructions, diverticuli, carcinoma, cardiospasm, etc., of the esophagus, in which locality the shadows gave the best information. The *x*-ray had changed their ideas regarding the position and relation of the stomach to habitus, tonus, and atony. The findings in gastric ulcer were dependent upon the location of the ulcer. Ulcer was indicated by localized spasm, delay in filling, incisura, and functional hour glass stomach. There was delayed motility in ulcer, the food remaining in the stomach as long as forty-five hours in some instances. The author pointed out the relation of pressure sensitive points to *x*-ray findings, and illustrated the findings in gastric tumors by stereopticon views. He also illustrated the location of tumors in or contiguous to the stomach and of the correlation of clinical and *x*-ray findings. He also illustrated the use of the *x*-ray in duodenal lesions, in affections of the small intestine and in colonic affections. It was of special value to the surgeon in localizing gastric lesions and in the determination of their nature. By a judicious use of the *x*-ray the number of exploratory operations could be greatly limited. The *x*-ray to be really valuable must be used in connection with clinical findings; there was still need for conservatism and confirmation of the findings as knowledge of this subject was still incomplete.

The Permanent Place in Medicine of Radiography after a Bismuth Meal.—Dr. Russell H. Boggs and Dr. Joseph Foster of Pittsburgh, Pa., presented this communication. They declared that since antiquity intestinal poisoning as a fountain head of disease had been recognized, but chaos existed in the ideas of medical men as to its cause and treatment. In the last ten years—mostly in the last five years—by the systematic study of the alimentary canal after a bismuth meal, more actual usable knowledge had been gained regarding the true causes of bowel poisoning, and more genuine scientific advance had been made in the treatment of the condition than in all the centuries preceding. The authors then gave a lantern slide demonstration illustrating the normal position of the alimentary canal and variations from normal, and described the effects that followed the deviations from the normal. The treatment was both medical and surgical and should be checked up and controlled by the *x*-ray. The author gave a retrospect of the work done up to the present time and correlated it with his own experience.

Dr. Chevalier Jackson of Pittsburgh, Pa., said that in regard to the gastroscope it was idle to say that the technique was easy to any one unless he had been trained in the details of gastroscopy. The difficulties were twofold, instrumental and technical; Dr. Janeway had overcome the instrumental difficulties and his instrument was practical. The stomach was in constant motion and it was difficult for the inexperienced to get much information, but the carefully trained worker could see a great deal. The man who would operate the gastroscope successfully must be a trained mechanician. There were many technical difficulties which could not be overcome without instruction and experience.

Dr. John Draper of New York said he had watched the development of Dr. Satterlee's work in water-trap stomach and had come to look upon the condition as a morphological entity. He had examined one hundred stomachs after death and found that the variations were greater than was shown here. Water-trap stomach differed from ordinary dilated stomach. Dr. LeWald had suggested that it had an origin similar to inguinal hernia, a congenital potential defect which did not show itself until some other factor was added. The symptoms began when the stomach had a residue, but the symptoms were not due to the residue, but seemed to be dependent on enzyme exchange. When the food was delayed in the stomach the water was absorbed, thus interfering with the enzymes causing peristalsis, and leading to the train of symptoms found in water-trap stomach.

Dr. Lewis S. Cole of New York said that he had seen Dr. Janeway make gastroscopic examinations and he had been able to do this with less discomfort to the patient than was incurred in an ordinary cystoscopic or urethroscopic examination. It was remarkable the way in which the gastroscopic findings dovetailed with the *x*-ray and supplemented it. The combination of the gastroscope with the *x-ray* excelled all other methods.

Dr. M. L. Graves of Galveston, Texas, said that great conservatism was necessary in interpreting the findings by these methods. They should be followed up by observations at the time of operation. If the stomach was dilated with atmospheric air the *x*-ray showed the dislocation if one existed. Most of the cases diagnosed as water-trap stomach would have pyloric opening or duodenal fixation and it was easy to diagnose them with the *x*-ray, but another class of cases had mobility of the pyloric end and a ptosis and they were not normal, as Dr. Mills had suggested, but represented a pathological condition.

Dr. Fenton B. Turck of New York said that this presentation was important to both the surgeon and the physician. Attention had been called to the congenital chracter of this condition. They had produced practically the same results in dogs as the result of fatigue. In their studies on chronic fatigue they had used forced feeding and overloading the stomach and produced chronic fatigue which resulted in a condition analogous to the water-trap stomach. This seemed to show that treatment along the lines of rest and exercise was logical. Purely mechanical treatment failed unless rest and exercise were brought to its assistance. Food should be withdrawn at first; then one meal a day was permitted, and later two, but never more than two meals a day. The exercise was given by means of air injections. The colon should be treated at the same time; in addition measures of general hygiene should receive attention. These usually effected a cure unless mechanical obstruction was present. This was a physiological condition and should be treated by physiological methods and not by mechanical means.

Dr. Henry H. Janeway, in closing the discussion, cautioned his hearers against too much hopefulness in regard to the gastroscope. It was a practical method and was applicable to the diagnosis of cancer in the early

stages. The question arose as to how early the patient with cancer complained of discomfort and it was his belief that most of these cases came under the eye of the physician early in the course of their disease. It was perfectly possible to remove a specimen of the growth within reach of the instrument, and he had diagnosed twenty-five cases of cancer in this way up to the present time; this diagnosis had been confirmed by the pathologist. Local anesthesia was possible in the vast majority of cases.

Dr. G. Reese Satterlee of New York, in closing the discussion, said that he was glad to see the trend of opinion toward the belief in the embryological causes of this condition. The water-trap stomach was not an enteroptic type. They did not want the impression to be conveyed that all water-trap stomachs required operative treatment. They required operation only when the lesser curvature was below the umbilicus. As mentioned before there was no one normal type of stomach; the stomach fitted the shape of the body, and thus one learned to diagnose the water-trap stomach by the build of the patient and especially by the long narrow thorax. In regard to the medical treatment he cited the case of a woman who without any abdominal support, but by raising the foot of the bed, lying on the right side after meals and attention to hygiene, had been relieved of pain, nausea and eructations and had gained eighteen pounds in four months.

Dr. L. T. LeWald said he could not understand the great discrepancies between the *x*-ray findings and the findings at operation referred to by Graves. He had seen some apparent discrepancies; like hernia the stomach might be reducible. When the patient was in the recumbent position it went up into a better position, but it could be drawn down.

Dr. R. Walter Mills called attention to the loose way in which the term enteroptosis was used. It was employed to indicate ptosis, atony, and dilation. Much difficulty could be saved by regulating the use of this term. During anesthesia, when the abdomen was opened, the tonus was lost and injections of the stomach in the cadaver gave false impressions. The basis of everything was the ability to study the individual stomach and to realize that the individual stomach fitted the individual body.

Cause and Treatment of Diarrhea.—Dr. Richard C. Cabot of Boston, Mass., read this paper. He said there were three general questions to be answered. What lesions of the intestines were associated with diarrhea and how often? What clinical features were associated with each lesion? What was the prognosis and treatment of diarrhea? In his consideration of the subject he excluded diarrheas incident to typhoid fever, those common only in the tropics and those epidemic in character. In making a distinction between the acute and chronic types of diarrhea Dr. Cabot said that chronic enteritis might present acute symptoms or a long standing diarrhea might be without organic basis. He had made a careful study of the relation of food indiscretions to diarrhea and had come to the conclusion that this factor was greatly overestimated. Ptomaine poisoning was an expression sadly misused; this had become a fashionable diagnostic term, which was usually found to mean acute pancreatitis, gallstones, etc. It was a condition very much rarer than was supposed. Diarrhea was infrequent in tuberculosis of the intestines and the latter was usually secondary to tuberculosis of the lungs. Mucous colitis was a neurosis with the fixed habit of examining the stools and bringing samples to the doctor. It was accompanied in three-fourths of the cases by constipation; it was rarely a diarrhea and never a colitis. Dr. Cabot had made a study of the record of 3,000 cases in Bellevue Hospital and a like number in the Massachusetts General Hospital. He found diarrhea present in acute and chronic enteritis in 40 per cent. of the cases in Bellevue Hospital and in 45 per cent. in the Massachusetts General Hospital; where there was disease of the colon he found diarrhea present in 52 per cent. of the cases in Bellevue Hospital and in 32 per cent. in the Massachusetts General Hospital; in tuberculosis of the intestines he found dirarhea present in 29 per cent. of the cases in Bellevue and in 32 per cent. in the Massachusetts General; in tuberculosis of the lung it was present in 15 per cent. of the cases in Bellevue and in 11 per cent. of the cases in the Massachusetts General Hospital. Out of 725 cases of diarrhea in the Massachusetts General Hospital, 473 occurred in acute enteritis, 130 in chronic enteritis, 76 in cancer of the colon, 25 in tuberculosis of the bowel, 15 in Graves' disease, 14 in pernicious anemia, 10 in mucous colitis, 9 in amebic dysentery, 7 in fat intolerance, and 6 in nervous hyperperistalsis. Compensatory diarrhea as a feature of chronic nephritis had not been established. It was difficult to tell from the symptoms whether the small or the large intestine was affected. If the rectum was affected there was tenesmus. Stool examination was valuable in prognosis. The duration of the diarrhea did not run parallel with the severity of the lesion. The prognosis was more grave where there was ulceration. As to the prognosis of the chronic cases they had been unable to cure 40 per cent., while in 60 per cent. the diarrhea had been checked, though they were not sure that it had been permanently cured. As to the treatment, when there was a history of severe intractable diarrhea, the patient was put to bed and twenty-four hours consumed in making the necessary examinations. The patient received no medication during this twenty-four hours and often at the end of that time there had been no movement of the bowels; this happened so frequently that they were forced to the conclusion that rest in the recumbent position was a most potent influence in chronic diarrhea. In acute case starvation combined with purgation was the treatment; there was nothing new in the method of purgation. The diet was largely nitrogenous, omitting the carbohydrates and fats for a short time. The psychic side of the question was more important than was generally recognized. Dr. Cabot cited the instance of 125 men suffering from diarrhea who belonged to the United States Army who were taken aboard a transport in Cuba. Inside of two days many of them had broken into the larder and had eaten bread and butter and the diarrhea had stopped in all but a few cases. They had received no treatment. The great factor here was psychic; they thought they were going to die in a foreign country, but when there was hope of home, together with the influence of the sea air, they quickly recovered. In long standing cases irrigations with normal saline solution were effective. A weak solution of silver nitrate was sometimes beneficial; however, if the first injection did not afford relief there was no use in repeating the dose. Emetine had given the same results as were previously mentioned. Bismuth in large doses was sometimes beneficial. There was no benefit to be derived from opium in the chronic or ulcerative cases. Sodium salicylate gave relief in a few cases.

Dr. W. S. Thayer of Baltimore said that in a large proportion of the cases of diarrhea it was not possible to name the cause and this was what they wanted to find out. The stools should be examined with care, as one often got hints in regard to treatment from the character of the stools. It had been demonstrated that diminished gastric acidity or anacidity was a common cause of peristent diarrhea. In such cases large doses of hydrochloric acid were indicated. In these cases one would expect to find a large amount of fatty acids in the stools, associated with diminished gastric secretion. In cases of mucous colitis all were familiar with the nervous attitude of the patient. This was one of the most interesting conditions with which they had to deal, not because of the mucous colitis but because of the associated condition. Mucous colitis might often be found to be due to mental and physical strain. If one studied the general conditions surrounding the patient he could often do much good. These cases often depended upon small local infections. Mucous colitis was commonly associated with constipation with occasional outbreaks of diarrhea. He emphasized what Dr. Cabot had said in reference to rest in bed in the recumbent position. The results of this factor in the treatment agreed with the suggestion that fatigue played a part in the etiology of mucous colitis.

Dr. P. S. Roy of Washington, D. C., called attention to the fact that hydrochloric acid controlled the opening and closing of the pylorus and this had much to do with the diarrheal attacks. He agreed that fatigue might be a cause of diarrhea; the diarrhea of exophthalmic goiter was a fatigue diarrhea and that was why rest was so important.

Dr. F. M. Pottenger of Monrovia, Cal., said that diarrhea in tuberculosis did not mean that there was tuberculosis of the intestines. Tuberculosis of the intestines might be present when there was no diarrhea. In open tuberculosis the tubercle bacilli were frequently found in the stools and this did not mean tuberculosis of the intestines.

Dr. J. S. McLester of Birmingham, Ala., spoke of diarrhea in connection with pellagra. This disease was usually recognized by changes in the mucous membrane of the mouth and by the patella reflex. The examination of the stools gave no help. It was possible that the diarrhea of pellagra had as its basis a nervous disturbance. Most of these cases had a lowered gastric acidity and hydrochloric acid checked the diarrhea.

Dr. Seale Harris of Mobile, Ala., said that diarrhea associated with pellagra was more frequent than supposed.

In Chicago only nine deaths had been attributed to pellagra and he believed that the number must be much larger, and that many cases passed unrecognized. In many patients suffering from pellagra the only symptoms were those of a gastrointestinal nature as diarrhea, stomatitis and burning in the abdomen and rectum. Three-fourths of the patients suffering from pellagra and having diarrhea had lowered gastric acidity or anacidity. In cases in which there was no decrease in acidity constipation was noted. The treatment of diarrhea associated with pellagra consisted in abstinence from corn products, rest, and the administration of hydrochloric acid. The diet should be largely nitrogenous.

Dr. Fred W. Bailey of Cedar Rapids, Iowa, said he was glad Dr. Cabot had been an iconoclast with reference to the ptomaine poison fad. He hoped he had dealt this fad a death blow.

Dr. Richard C. Cabot of Boston, in closing the discussion, said that the question of achylia gastrica was not so simple as it appeared. In the achylia of pernicious anemia they had the achylia present all the time but not the diarrhea, hence there must be another factor involved. Mucous colitis and morning diarrheas were to be cured by psychic methods, or change of environment. Achylia gastrica seemed to have no direct relation to Graves' disease; sometimes it was present and at others not. The most impressive cures in mucous colitis were effected by encouragement and stuffing.

Cerebrospinal Fluid in the Diagnosis and Treatment of Syphilis.—Dr. Walter V. Brem of Los Angeles, Cal., presented this paper, in which he discussed the relation between the Wassermann reaction in the blood and in the cerebrospinal fluid and the relation between the Wassermann reaction, cell count, and butric acid test in the cerebrospinal fluid. The examination of the cerebrospinal fluid was the criterion of the cure of syphilis. Parasyphilitic and metaspyhilitic affections were really active syphilitic processes. The problem was to prevent local lesions in the central nervous system. The Wassermann test might be negative in the blood when it was still active in the cerebrospinal fluid. It was possible to have a positive cerebrospinal reaction when there were no symptoms of syphilis. Before a case of syphilis was pronounced cured it should be demonstrated that the cerebrospinal fluid was negative. The incipient cases of paresis were the ones that showed the greatest improvement under this treatment. He administered one-tenth of a gram of salvarsan to every 20 pounds of body weight. He had given as much as eight-tenths of a grain intravenously. The reaction was stronger than from smaller doses. After the reaction became negative he gave three additional doses together with a course in the mercurials.

Dr. A. R. Dochez of New York said that lumbar puncture should be practiced more frequently in syphilitic cases. It had been found that a persistent Wassermann reaction was often due to infection of the central nervous system. In treating syphilis it was not an uncommon practice to wait for a positive blood reaction, but this did not appear until six days after the initial lesion. The appearance of the Wassermann reaction and secondary manifestations showed that the infection had become a general one. A diagnosis should be made early and the disease treated before it became disseminated. This could be done by making a dark field preparation from the lesion. The great frequency of the involvement of the central nervous system suggested the importance of making lumbar puncture in every case of syphilis.

Dr. Richard C. Cabot of Boston called attention to Homer Swift's method of injecting salvarsanized autoserum into the cord; he injected 30 c.c. of the patient's own salvarsanized serum. One should assume the involvement of the central nervous system until it was proved to the contrary.

Dr. Frederick F. Russell of Washington, D. C., said that he thought they now had a standard for the cure of syphilis. They had several things upon which to rely; the length of time without symptoms should be one year; there should be no positive Wassermann reaction during one year, and negative spinal reactions at the end of a year.

Dr. J. S. McLester of Birmingham, Ala., said they had followed the Swift method in parasyphilitic affections. They injected salvarsan intravenously and then after one-half hour drew the blood and reinjected 30 c.c. of the serum intraspinously and they were elated over the results.

Dr. Brem of Los Angeles, Cal., said that he had referred to Swift's method in his paper and that it might prove the method of choice, but he hoped that the method of giving large doses of salvarsan would prove effective, as it was simpler and would reach a larger number of individuals.

The afternoon session was devoted to a symposium on leprosy.

Dermatological Aspects of Leprosy.—Dr. Isadore Dyer of New Orleans read this paper. He divided these cases into the following nine groups: (1) Macular. There was a general impression that the individual was carrying in the circulation the infection which was the cause of the disease. The eruption was not at all characteristic, but quite evanescent. It occurred usually over the back of the hands and on the legs and was brownish in color. Some of these patches were anaesthetic, and others were not. It was quite easy to demonstrate the lepra bacillus in these cases. Macular leprosy should be differentiated from syphilis and erythema multiforme. In the latter, the eruption lasted for many months. (2) Tubercular. In this class there were two forms, the large and the small. In the former the color was quite characteristic, being a brownish-red. Both lupus and syphilis might be confused with this form of leprosy. The small tubercles were dirty-yellow in color and the condition grew rapidly in its course. The lesions were likewise anaesthetic. (3) Bullous. The lesions appeared most often in the hands and feet and deformities resulted from the loss of bone resulting from ulceration. The ulnar nerve was usually involved in this. (4) Pigmentary leprosy. (5) Nodose leprosy. This was usually facial and the features were much changed because of the resulting necrosis. (6) Scaly epilepsy. This was a very rare condition. Peripheral nerve changes were found at the same time with the scaly condition. (7) Ulcerative leprosy. The lesions were usually located on the soles of the feet. (8) Mutilating leprosy. In this form the lips dropped off, as well as the fingers and toes; the fingers and toes, one by one, falling off. In this form exacerbation occurred, and there was a rise of temperature producing the so-called "fever of leprosy." (9) Papular form. By studying and learning the lesions occurring in leprosy it was possible to recognize this disease by differentiation. The diagnosis meant so much in the care and the cure of these patients. Dr. Dyer gave an interesting lantern slide demonstration which showed the different forms of leprosy and also the conditions with which they were liable to be confused.

Clinical Aspects of Leprosy.—Dr. E. Boeckmann of St. Paul, Minn., read this paper. He first showed how the disease affected the muscles of the face causing atrophy, especially of the masseters. It then affected the extremities, and produced the characteristic walk. The skin lesions exposed the patient to many injuries and infections. The author followed the course of the disease until it reached the stage of purulent periostitis, necrosis of the bones, and finally dropping off of fingers, toes, eyelids, etc. One peculiar feature of the disease was that the mucous membrane of the nose and throat remained intact until late in the course of the diseases.

Bacteriology and Specific Therapy of Leprosy.—Dr. C. Duval of New Orleans, La., not being present Dr. Isadore Dyer read his paper. He said that since the discovery of the Hansen bacillus in 1879 many attempts had been made to cultivate the bacillus. The casual relation of the Hansen bacillus to the human disease had been established. There was much difference of opinion as to the botanical status of the bacillus. It was now possible to grow the bacillus outside the body, and his oldest cultures of this germ in purity were now three years old. The bacilli could not be grown on the ordinary media used by bacteriologists, the media must contain the split products of protein obtained by decomposition. The bacillus was first grown on bits of leprous nodule obtained from the human body and planted onto an agar medium in alkaline reaction. The bacilli grew very slowly, requiring from eight to ten weeks to develop. The author drew a comparison between the lepra bacillus and other acid fast saprophytes and with the tubercle bacilli.

Public Health Aspects of Leprosy in the United States.—Dr. Rupert Blue presented this paper, which, in his absence, was read by Dr. W. C. Rucker. He stated that on account of the communicability of leprosy it was a disease that should cause common concern. It existed in many States and insular possessions of the United States. There were four leprous areas in the United States: the Atlantic seaboard; Gulf States; Pacific Coast, and in Minnesota. There were 146 cases under control in 1912. In all there were so far as could be found out 3,224 cases in the United States and its possessions, there being 2,754 cases in the Philippines. The author reviewed the various measures which Congress had passed for governing the exclusion of lepers from the country and providing for

their deportation, and also the measures regulating their interstate transportation. It was pointed out that there were too few cases at present to warrant the establishment of a leper colony in each State, but that a single colony under federal control was the most desirable method of providing for the proper care and segregation of the victims of leprosy. The great stumbling block in the way of such an institution was the fear of each congressman that the institution might be located in his State. Owing to the long incubation period of the disease it was exceedingly difficult to measure its progress, but there were reasons to believe that if it was not properly controlled during the present generation it would become a much more serious problem by the end of one hundred years. The disease was being studied in government laboratories in Hawaii and Molokai. Different States were dealing with the problem in different ways. In Minnesota they practiced self isolation; in Massachusetts and in Louisiana provisions were made for segregation; in Hawaii and the Philippines segregation was more or less effectively enforced. Some localities, notably New York, purposely avoided the problem.

Dr. H. M. Bracken of Minneapolis, Minn., said there were now sixteen known cases of leprosy in his State, seven of whom were born there. The disease was not readily communicated and there was no danger of infection from street cars, railway cars, or in public places. In Minnesota the cases were cared for in their own homes if the patients were in comfortable circumstances and able to use the ordinary precautions.

Dr. M. L. Graves of Galveston, Texas, and Dr. G. H. Sumner of Des Moines, Iowa, spoke in favor of a national leprosarium.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY.

Dr. F. F. Simpson of Pittsburgh in the Chair.

Tuesday, June 17—First Day.

Chairman's Address: Right-sided Hypertension with Occasional Cardiac Dilatation as Postoperative Complications.—Dr. F. F. Simpson of Pittsburgh related his experience and observation both in experimentation on dogs and in his surgical practice as regarded the effect of position, intravenous injections, anesthesia, etc. Large injections of saline solution into the jugular vein, and the long continuance of the Trendelenburg position were two things that produced hypertension and dilatation. If the heart condition was good to begin with, the results following such strain were not especially bad; but if on the other hand there was a tendency to a weakened condition of the heart walls, there was evidence of acute dilatation following operation. In a series of 102 cases there were no deaths due to such ill effects. The treatment was elevation of the head of the bed and the administration of heart stimulants.

Some Newer Methods of Reducing the Mortality of Operation on the Pelvic Organs.—Dr. George W. Crile of Cleveland read this paper. He stated that whereas uncomplicated operations for fibroids, chronic pyosalpinx, benign tumors of the ovary, procidentia, prolapse, etc., called for no special discussion, because they were all easy risks, they might become formidable operations if performed on patients with too high or too low blood pressure produced by infection, hemorrhage, or other causes. The experienced surgeon had learned to select his patients according to what he knew he was able to do, and oftentimes the handicapped patient was turned aside because, for want of method, the operation could not safely be performed. The purpose of the paper was to show that nearly all such patients might be reclaimed and operated upon safely. Some eight thousand abdominal operations furnished the basis for study. In his paper Dr. Crile went into the effect of nervous strain, anesthesia, vomiting, and nausea, and showed by means of latern slides, the changes that took place in the cells of the brain when exhausted or fatigued. His method of operating under novocain injections locally he believed to be responsible for a greatly reduced mortality in his surgical work. In four years it had dropped from 6 per cent. to 1 per cent.

Postoperative Renal Infection.—Dr. Henry Dawson Furniss of New York stated that this condition occurred oftener than was generally believed, which explained many otherwise unaccountable postoperative temperatures, inflammatory bladder complications, and other urinary troubles which might follow some time after the patient was supposed to have recovered from the operation. While such infection might arise after any operation, it was more apt to occur with surgical procedures on the intestinal tract. He believed that the inactivity of the bowels of patients lying in bed, or even catharsis practised to overcome this inactivity, accounted for many colon bacillus infections.

Dr. Draper Maury of New York, in discussing this paper, said that he and Dr. Braasch of Rochester had carried out a number of experiments on dogs in which they tried various means to produce postoperative urinary infection, but were never able to cause an ascending infection of the kidney.

Final Results Following Operations for Ectopic Pregnancy.—Dr. Richard R. Smith of Grand Rapids, Mich., read this paper. Taking 193 women on whom the operation had been performed five or more years before, he had inquired as to whether these patients had borne children, or had had a repetition of the ectopic pregnancy. In his questionaire he sought to bring out whether or not the prevailing custom of leaving the opposite tube, if it were healthy, was rational. His conclusions were that the age of the patient, her social condition, and the number of children she had already borne, should determine whether the opposite tube should be left or removed. Of the 193 cases inquired into, 53 were not able to have children, leaving 140 who could have had as far as one might say. Forty-one of these did bear subsequent to operation. Twenty-one suffered a second time from ectopic gestation.

In the discussion which followed the general opinion was that if the other tube were healthy it should not be removed. At any rate it ought not to be removed unless the patient and her husband demanded it, rather than run the risk of a repetition of the trouble.

The Movable Kidney.—Dr. J. H. Carstens of Detroit read this paper. Various degrees of mobility all produced symptoms. Mechanical support did give some relief, but the only permanent cure was by proper surgical fixation. He thought that many of the symptoms were due to a disturbance of the solar plexus.

Dr. Hall of Cincinnati, who had operated on many patients stated that in many instances his work had been followed by disappointment—the kidney would not stay fixed nor would the symptoms always disappear.

Dr. Goldspohn of Chicago believed there were cases of displaced kidney that really demanded operation and were benefited thereby. His way of determining whether a given case would be helped by surgery was to apply a very uncomfortable belt to the patient that would mechanically help to hold the kidney in place. If the patient admitted that she felt better with this device pressing into her abdomen than she did without it, he was satisfied that operation would effect a cure.

Further Points on the Sterility of Women.—Dr. Edward Reynolds of Boston read this paper, dividing the subject into (1) those cases which are dependent on conditions of the secretions; and (2) ovarian conditions which result in a failure in the release of the ovum. Of the first he mentioned the altered condition of the mucous membrane and the altered condition of the vagina, cervical canal, endometrium, and tubal mucous membranes. His treatment was chiefly one of drainage. Of the alterations of the ovaries as a cause of sterility, he spoke of a thickened capsule, multiple retention cysts, and persistent corpora lutea.

Dr. Frank of New York thought perhaps Dr. Reynolds placed too much importance on the effect of secretion, especially vaginal, and cited instances in which conception took place under all manner of disturbed mucous membrane secretion. He mentioned one case in which conception took place through a uterovaginal fistula. In his study of the subject he was of the opinion that ovarian and uterine conditions were the most frequent causes of sterility.

Dr. Bacon of Chicago said he had used the extract of corpus luteum with some degree of satisfaction in conditions of sterility.

Dr. Jacobson of Toledo thought a great deal depended on the patency of the Fallopian tube.

Wednesday, June 18—Second Day.

Prolapse of the Uterus: Its Surgical Treatment.—Dr. Franklin H. Martin of Chicago advocated the interposition of the uterus below the bladder and beneath the anterior vaginal wall in women past the menopause. Amputation of the cervix was recommended to be done at the same time, especially if it were long. The same operation was recommended in extreme cases with the additional procedure of sterilization if the woman were past forty years of age. At the same time the floor of the pelvis should be restored when necessary in order to overcome prolapse of the lower rectum.

Vaginouterine Prolapse and Its Efficient Treatment.—Dr. E. E. Montgomery of Philadelphia read this paper,

in which he discussed the form of prolapse through the vaginal outlet, denominating the condition as a hernia of the bladder, rectum, and vagina, accompanied or not by the uterus. The fundus of the uterus might maintain its position although the supravaginal portion of the cervix had become attenuated, permitting the external os to form the most dependent part of the protrusion. He believed that greater comfort to the patient could be secured if the uterus were removed, and, to secure the best results, the bladder and rectum must be widely separated from their relations, the one supported on the overlapping broad ligaments, the other held up by the rectovaginal interposition of the levator ani muscles. It was also recommended that redundant portions of the vaginal walls, both front and back, should be removed.

The Anatomy and Surgical Utility of the Sacrouterine Ligaments.—Dr. GEORGE B. SOMERS of San Francisco presented the subject from an anatomical and mechanical standpoint. Little attention was paid to these ligaments, and their surgical utility was not well defined.

A Study of the End-Results of the Webster-Baldy Operation.—Dr. JOHN OSBORN POLAK of Brooklyn reviewed the basic principles of uterine support, and showed wherein the Webster-Baldy operation failed. He thought that in many instances it was due to faulty technique. The procedure commonly had the effect to draw the fundus of the uterus forward and downward. His observations were based on several hundred cases, quite a number of which had subsequently undergone another operation. Many of the women became pregnant after the operation, suffering no unusual inconvenience therefrom.

Tuberculous Salpingitis.—Dr. PHILEMON E. TRUESDALE of Fall River, Mass., brought out the insidious origin, period of occurrence, relative frequency, and the difficulties in making an early diagnosis. Very commonly the condition was discovered on the operating table when the abdomen was opened, perhaps for some other affection. He laid great stress on the importance of family and social history, declaring that the various tests for tuberculosis were unreliable. He believed the exploratory incision was warranted in doubtful cases, and early operative treatment was necessary if a cure was to be hoped for. In early cases the procedure was simple, but became difficult and dangerous later. Only in mixed infections would he close the abdomen with drainage. Slow healing was the rule. The after-treatment should be based on the best hygienic principles.

Dr. CARSTENS of Detroit criticised the operation and could not see why a "little insignificant tubercle" on the tube should be so radically attacked when similar tubercles were allowed to remain in countless numbers in the peritoneal cavity.

Dr. MURPHY of Chicago insisted that since the focus was in the tube and since the tubercles extended from that point the diseased oviduct should be excised.

Infections of the Pelvis from a General Surgeon's Point of View.—Dr. JOHN B. MURPHY of Chicago contended that every labor and abortion should be considered as a surgical procedure as far as the dangers and conditions of infection were concerned. He divided the avenues of infection into perineal, vaginal, cervical, fundal, and tubal, the route of transmission from the point of infection being along the lymphatics, veins, and arteries, and by contiguity of surfaces. The infective microorganisms commonly were carried to the primary vaccination direct, but might be carried by indirect or hematogenous routes. He compared an infection within the pelvis to one of the arm or other exposed surface of the body, and said that it should be viewed in very much the same light Specific and not generic terms should be used in discussing and considering pelvic infections, and since they were similar to or identical with the processes that took place elsewhere in the body, the treatment should be based on the same surgical principle.

Thursday, June 19—Third Day.

Report of Committee on the Question, "Should the Puerperal Uterus Be Emptied of Ovicular Remains in the Presence of Infection, and if So, When?"—Dr. JOSEPH B. DE LEE, Chicago, reported that a series of questions had been sent to several hundred obstetricians and surgeons, Europeans as well as Americans, from whose replies he had drawn certain conclusions. The result of his inquiries had been good. His questionaire contained several items, the chief of which were the treatment of the uterus (1) when it contains an intact, but infected egg; (2) when the fetus has escaped but the placenta is retained; (3) treatment of a patient after full-term delivery, with an infected piece of placenta retained. In the main, obstetricians, general surgeons, and the general practitioners answered the questions alike, the preponderance of opinion being that the uterus should be emptied, the dull curette, the finger, or the placental forceps being used. He gave as his own opinion that in septic abortion one should try to determine if there be any perforation of the uterus, since such a complication often accompanied induced abortions. If satisfied that the infection was confined to the cavity, he first packed the vagina with iodized gauze and later cleaned out the uterus. The treatment was practically the same for propositions 1 and 2, but, in case of puerperal sepsis, he would not invade the cavity of the uterus; indeed, he is very much afraid of such interference. Of the curette he said that while it might be used in abortions, he never employed it after labor. As to the use of serums, he believed them practically valueless. In short, his management of sepsis was expectant and conservative rather than specific and active.

Care of the Umbilical Stump: A Bacteriological Study.—Dr. FRED L. ADAIR of Minneapolis called attention to the importance of treating the umbilical cord aseptically. It should be handled as carefully as a wound. He believed that fever and jaundice of the newborn oftentimes are due to infection entering through the umbilical vessels. A series of observations were made, both clinically and by culture, which seemed to prove that fewer infants suffered from morbidity whose umbilical stump was treated with alcohol and tincture of iodine than did those who simply had a sterile dressing applied.

Dr. HEANEY of Chicago believed the stump should be left an inch or more long, claiming that it separated and dropped off in a shorter time than when ligated close to the abdomen.

Local and Spinal Anesthesia in Gynecology and Obstetrics.—Dr. GEORGE GELLHORN of St. Louis read this paper, maintaining that for minor gynecological operations such as curettage, dilatation, trachelorrhaphy, and amputation of the cervix, local anesthesia was all-sufficient, and when such operations preceded laparotomies, its use materially reduced the amount of ether required. To diminish pain during the first stage of labor, he recommended the injection of novocain into the cervix.

Spinal Anesthesia in Gynecology, Obstetrics and Abdominal Surgery.—Dr. W. WAYNE BABCOCK, Philadelphia, based his observations on over two thousand cases in which spinal anesthesia was employed. The most marked effect was the influence it had on the cardiovascular system, and he specially warned against its use in conditions of low blood pressure. He spoke of the marked relief from ileus that followed spinal anesthesia.

Dr. HERTZLER of Kansas City left it to the patient whether general or spinal anesthesia should be employed.

The Thyroid Gland and Its Degeneration in Relation to Obstetrics and Gynecology.—Dr. CHANNING W. BARRETT of Chicago read this paper. In it he discussed the biology, embryology, physiology, and anatomy of the thyroid gland as it related to the reproductive organs. From analogy he concluded that, from the close anatomical relation between the thyroid and the uterus observed in some animals, there must be a mutual influence between the two organs. From a physiological standpoint he called attention to the preponderance of enlargements, degenerations, and vitiated activities of the thyroid gland of the female; its correlation with puberty, menstruation, marriage, excessive coitus, sexual desire, and pregnancy.

Case of Lymphangioma Resembling Hernia of the Lung.—D. C. L. Fitzwilliams reports the case of a boy aged six years, whose mother had noticed that something was wrong with the right side of his neck when he cried. She states that she noticed this vaguely when she was washing the child, and she can recall it as far back as twelve months ago, but she took little notice of it until it began to get larger during the last three months. In November the child got whooping cough and this lasted until the end of December. During this time his mother noticed that the lump in his neck got very large during the spasms of coughing. On examination, there is a fullness of the root of the neck above the right clavicle and behind the sternomastoid muscle. It is all defined and quite soft, and small nodules can be felt in it. It seems to disappear under the fingers toward the region of the subclavian artery. On coughing or straining the root of the neck fills up and bulges in a prominent manner, and on palpation the tumor again subsides. Percussion is unsatisfactory as there is so little resistance, and though breathing sounds are heard they are probably transmitted The condition at first sight is extremely like a hernia of the apex of the right lung, but there is no indrawing on deep inspiration, nor can any ring be felt in the deep part of the neck.—*Proceedings of the Royal Society of Medicine.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

	Orthopedics	Dr. Truslow	9:00 A.M.
	Orthopedics	Dr. Napier	2:00 P.M.
Coney Island Hospital	Pediatrics	Drs. Beck, McQuillan, Pendleton and Van Wart	3:30 P.M.

THURSDAYS

City Hospital	Gynecology	Dr. Stearns	2:00 P.M.
Cumberland St. Hospital, Brooklyn.	Gynecology	Dr. Burnham	1:00 P.M
	Surgery	Dr. Walmsey	3:00 P.M.
	Laryngology and Rhinology	Dr. Stewart	4:00 P.M.
Kings County Hospital, Brooklyn	Otology	Dr. Alderton	1:00 P.M.
	Surgery	Dr. Barber	2:00 P.M.
Coney Island Hospital	Gynecology	Drs. McEvitt, Mills, Mayne and Rankin	10:30 A.M.
	Surgery	Drs. Fiske, Bogart, Murphy and Lack	3:00 P.M.

FRIDAYS

City Hospital	Laryngology and Rhinology	Dr. Dougherty	2:30 P.M.
Neurological Hospital.	Neurology	Dr. Abrahamson.	9:00 A.M.
Cumberland Street Hospital, Brooklyn.	Ophthalmology and Otology	Dr. Warner	3:00 P.M.
	Surgery	Dr. Iler	3:00 P.M.
	Surgery, Oral	Dr. Shea	4:30 P.M.
Kings County Hospital, Brooklyn	Gynecology	Dr. McNaughton	9:00 A.M.

SATURDAYS

Neurological Hospital.	Neurology	Dr. Walsh	2:00 P.M.
Kings County Hospital, Brooklyn.	Surgery	Dr. Barber	11:00 A.M.

All registered physicians, visiting and resident, and medical students, are cordially invited to attend these clinics.

Cards of Admission, valid until October 1st, 1913, may be obtained at the Academy of Medicine, 17 West 43rd St., Manhattan, and at the Medical Society of the County of Kings, 1313 Bedford Avenue, Brooklyn, as well as from the Secretaries of the several Medical Colleges.

METABOLISM AND THE CIRCULATION.

By ALEXANDER HAIG, M.A., and M.D. Oxon, F.R.C.P.,

LONDON, ENGLAND.

CONSULTING PHYSICIAN TO THE METROPOLITAN HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.

It must be obvious to anyone who thinks for a moment, that the circulation controls the life of the whole body. Block an artery, the part it supplies passes into gangrene. Press on an artery, the parts for a time become poorly nourished. When capillaries are blocked and the circulation through them is slowed to one-half of its ordinary rate we get cold extremities, swelling, edema, chilblains, dead hands, and other phenomena showing serious alterations of nutrition in the affected parts. Life is circulation; apart from it there is no continuing life. The better the circulation the better the life.

Then if we look at the functions of such organs as the skin, the heart, the kidneys, the liver, the salivary glands, the stomach, and intestines, we see similar phenomena testifying in no uncertain manner to the fact that all their functions are most intimately related to a free circulation in their capillary vessels. The vessels which bring nourishment and oxygen and remove waste products, and generally provide for that life of the tissues from moment to moment which we call metabolism or combustion. The results being heat, brain-power, energy, in a word, life.

The skin, after exposure to years of defective capillary circulation, becomes yellow, harsh, rough, scaly, and dry, perspiring only slightly and with difficulty, it loses its natural soft, velvety texture, its glands atrophy, and, as I have proved, its thickness may diminish to one-half of that which is normal; and, as the skin is a most important organ of life's metabolism, such changes are a very serious matter for its owner.

The heart, though it is the great central driving power of the circulation, is, nevertheless, like the rest of the body, dependent on muscular nutrition, and the moment its driving power begins to fail from weakness or continued starvation (*e.g.* chronic under-feeding continued over months and years) its muscle fibres begin to suffer from defective nourishment, the nerve structures that regulate its movements begin to degenerate, and function falls off to a corresponding extent. Then there is no doubt that defective capillary circulation affects the structures of the heart just as it does those of the skin, leading first to debility, and then to atrophy and degeneration. Hence fatty degeneration of the heart is so common a sequel to a long-drawn-out battle against excess of waste products in the blood (collemia), which at one and the same time increase the work of the heart and diminish its power. Hence the deadly power of collemia in depressing the metabolism and combustion of the whole body.

The kidneys again yield most interesting testimony to the power and importance of capillary obstruction by waste products. For not only does the urine vary from hour to hour in direct relation to the amount of obstruction, but the chief nitrogenous excretion of the kidney (urea) is also controlled by it. This, of course, is not, strictly speaking, a kidney effect, for when urea is in solution in the blood it is under all conditions very promptly excreted by the kidney (except, of course, in collapse, when there is very low blood-pressure). But the control of urea excretion by capillary obstruction is due either to a defective formation of urea from its antecedents or to the temporary locking up of urea or its antecedents in the tissues and their interstitial fluids; but in either case this control of excretion is good evidence of the power of the circulation over metabolism. In Bright's disease, where we meet with this phenomenon to the most marked extent, anything that suffices to clear the blood of collemic obstruction (*e.g.* fever) is sure to be followed by a very marked rise in the excretion of urea, for circulation and metabolism are relieved, waste products are freely formed, and as freely removed from the tissues and excreted. But the same occurs in physiology every morning and evening throughout life, only to a smaller extent. There are always more waste products in the blood in the morning, and this is accompanied by a lessened excretion of urea, but anything that clears the blood of waste products at this time of day at once produces both a diuresis and a rise in the hourly excretion of urea, no food or fluid having been taken.

The clearing of the blood from waste products, as it occurs in the physiology of the daily round, is always accompanied by a feeling of increased power (muscular, nervous, and mental), for the capillary circulation in the organs that produce these feelings has improved, and the knowledge we thus obtain from the physiology of our daily life can be used practically to increase both the power and endurance of athletes and the brain-power of statesmen and orators, and many in both classes, without knowing the explanation of the facts, have used drugs (*e.g.* opium), which clear waste products out of the blood, for their bodily and mental effects. Mercury and other metals will produce similar results, and a course of salicylate does the same by removing most of the available urate from the body. Not only in physiology does the excretion of water from the kidneys vary from day to day and hour to hour with the quantity of waste products in the blood; not only does every diuresis occur when the blood is clear of uric acid, and scanty urine when the blood is loaded with it, but by controlling the

amount of uric acid in the blood we can make the urinary water anything we please, and this explains the action of all diuretic drugs. They all clear the blood of uric acid, and so freeing the circulation in the capillaries of the kidneys, allow water to pass out. If any such drug fails to affect the quantity of uric acid in the blood it also fails to alter the excretion from the kidneys; and this failure can be read in the rate of the capillary reflux, the condition of the blood under the microscope, and the excretion of uric acid and urine from the kidneys. If you diminish the uric acid in the blood you have diminished it also in the urine, and by such increase or diminution you alter the rate of the capillary circulation in the skin and throughout the body. Thus to touch the skin surface with the point of a finger, to squeeze it white and watch the rate at which the capillary circulation restores the color (capillary reflux) will tell you more about the physiology and pathology of the whole body than any other single observation. When you find a capillary reflux (C.R) of 6 or 7 half seconds you know that the physiology of the bodily circulation is not far from normal. If you find a C.R. of 2 or 3 half seconds you know that the patient has fever (unless there is local inflammation or venous obstruction at the point touched). If you find a C.R. as slow as 10, 12, or 14, and beyond, you know that he has some defective metabolism and combustion, and must look for such troubles as headache, epilepsy, mental depression, neurasthenia, weak or diseased heart, Graves' disease, Bright's disease, diabetes, etc.

Behind the quick C.R. of fever you may find gout, rheumatism, acute skin disease, specific fever, but not respiratory disease such as bronchitis or pneumonia, because in these the blood is not cleared of uric acid, as the acids, which are formed in ordinary fever, and clear the blood by rendering it a poor solvent of uric acid, are in these respiratory diseases not formed owing to lack of oxygen. We thus learn that fever quickens the C.R. only when it is able to clear the blood of uric acid by altering its alkalinity. Everything else that clears the blood of uric acid quickens the C.R. in the same way and to a more or less similar extent. But when there is dyspnea, acids are not formed in fever to the same extent, the alkalinity of the blood is not diminished, it is not cleared of uric acid, and consequently the C.R. is not quickened.

The liver again testifies to the power of the circulation by becoming larger or smaller with every change of blood-pressure. Not only does the liver get dark, hard, and congested in chronic morbus cordis, as we have all seen it in the post-mortem room, but every rise of blood-pressure which dilates the heart even for a few hours also enlarges the liver; every fall of blood-pressure which allows the heart to get smaller also reduces the size of the liver. So that in the liver we have a reliable index of all important fluctuations of blood-pressure and of their effect on the heart, *i.e.* of its strength. And so constant is this relation between the size of the heart and that of the liver that if I find an alteration in one of them without a corresponding alteration in the other I go over my measurements again to see that I have made no mistake. Just as C.R. is slower, B.P. higher, and heart larger every morning, so is C.R. quicker, B.P. lower, and heart smaller every evening, and with every fluctuation of these things, when well marked, there is a corresponding change in the size of the liver.

What applies to the liver applies also to the stomach, duodenum, and pancreas. When the liver is enlarged and congested, so are they. And when the duodenum is congested there is apt to be blocking of the ducts with diminished outflow of bile and pancreatic secretion as well as diminished excretion from other intestinal glands. Hence, as we know in chronic collemia, digestion may come to more or less of a standstill, and putrefaction take its place. Hence the stools passed in such conditions are not only deficient in bile, but extremely offensive. And here we see in full the causation of a so-called "bilious attack." A patient takes some excess of acid fruit, or exposes himself to cold, in either case he gets a retention (accumulation) of say five, ten, or even fifteen grains of uric acid; then if later on some condition, such as deficient food, dyspepsia from indigestible food, warm weather, or other cause of increased solubility of uric acid supervenes, some part of the quantity which he has accumulated by the retention is dissolved and passes into his blood, this obstructs the capillary circulation, enlarges the heart, congests the stomach, liver, duodenum, and pancreas, and the "bilious attack" is soon in full swing, as the result of the mechanical conditions above mentioned. Here we have a complete explanation of the fact that those who get uric-acid-free soon cease to suffer; for them such congestion of liver, stomach, and duodenum is no longer produced by changes of weather. Their circulation tells us why it is not.

Further, we know that under such conditions of collemia with capillary obstruction and secondary congestion of abdominal viscera the absorption of drugs ceases for a time, but begins again as the circulation returns to normal. This is well seen, for instance, in the natural history of the epileptic disturbance, which I have worked out at some length in my larger book on "Uric Acid," page 287 *et seq.* We now know that collemia plus heart failure is the cause of the epileptic attack as well as of the bilious attack, with the congestion of the abdominal viscera that often accompanies it. Hence the temporary cure of epilepsy by heart tonics, such as digitalis.

The salivary glands again tell the same tale, for in collemic conditions with obstruction of capillary circulation their excretion is diminished and the mouth becomes dry and sticky, thus exactly paralleling the excretion of water from the kidneys and the lungs under similar conditions. But take a dose of mercury, or, for that matter, anything that will clear the blood of uric acid, and the mouth becomes moist, just as the excretion of water from the lungs and kidneys increases. (See "Uric Acid," Ed. VII., pp. 318, 378, and 609.)

The record of the water excreted from the lungs shows that uric acid controls their entire capillary circulation, just as we already know that it does that of the rest of the body. In this way a diet which blocks their capillaries with uric acid exposes them to deficient removal of waste products, defective supply of nourishment, to various forms of chronic congestion, and so to microbic invasion. The microbes have their chance, and, as they are almost ubiquitous, they rarely neglect it. On the other hand, with the splendid capillary circulation, good nutrition, and efficient removal of waste products which are present throughout life in those who live on a sufficient quantity of natural food the microbes get no chance at all, but are quickly burned up in the fires of life; and this means the

exclusion not only of tuberculosis from the lungs, but also the absence of catarrh and various forms of pneumonia and congestion which did so much to favor microbic attack. (See "The Circulation as a Factor Which Determines the Effects of Microbic Invasion." MEDICAL RECORD, Sept., 1910; also "Gout of the Intestines," same journal, Oct., 1912.)

Then the effect of the circulation on the function of the brain is great and obvious, for we all know that the man with the quick C.R. takes a cheerful view of everything, while he with the slow C.R. cannot be cheered even by the greatest good fortune, so that the vast effect of capillary circulation on all the tissues of the body is obvious and can be completely demonstrated from hour to hour by the mental conditions alone.

Bad capillary circulation also causes anemia, as it no doubt hinders the functioning of the blood-forming glands, just as we have seen that it hinders the functions of the liver, pancreas, salivary glands, kidneys, and lungs. And so constant is this action that the condition of the blood over weeks and months is practically an absolute guide to the quantity of uric acid which is passing through it. Again, those who have good blood and a normal capillary circulation, do not harbor microbes, or allow of their multiplication, but quickly burn them up and get rid of them. This is the case with the microbes of such troubles as catarrh, influenza, malaria, tubercle. Catarrh does not touch those who are uric-acid-free, however much they may have suffered in their poison-taking days. It is the same with influenza, and malaria, if it touches them at all, it does so but lightly, so that the really uric-acid-free need not trouble about quinine and mosquito nets. Tubercle is cured by a free capillary circulation of good blood; and fresh air and double food are only a means to this end; but fortunately they are not the only means to that end so desirable in itself.

Natural food, free from poisons, and in sufficient quantity, always produces this good blood and free circulation, and all who have these and live a natural life in the fresh air are, I believe, immune to tubercle. But be this as it may, all the drugs that are useful in treatment have this result in common: —that they clear the blood of uric acid, and thus produce a free capillary circulation, and they at the same time directly or indirectly strengthen the heart if it has been weakened in the chronic fight against collemia. What is the use of the tonic so frequently used in phthisis, say nux vomica? Is it not to strengthen the heart and thus improve the circulation through the diseased lungs? What is the effect of fresh air and increased food but to clear the blood of uric acid and so again improve the circulation? Among drugs take, for instance, chloride of magnesium. I have proved that this clears the blood of uric acid, and under its use the consumptive patient exhibits an improving blood quality; he gains five, six, or more pounds in weight, after a time the bacilli disappear from the sputa, and the local lung condition becomes quiescent, and he appears to be on the road to recovery. It is said to cure in the course of nine months, but I have never seen a cured case, simply, I believe, because hospital patients, the only ones in whom I have been able to try it, are unable to continue the treatment for a sufficient length of time. Now in this treatment we produce for a short time, by means of a powerful drug, the very conditions, good blood and a quick circulation, which are permanent in those who live on a correct quantity of natural and nonpoisonous foods. We are here laboring hard with drugs, fresh air, and diet, to produce a condition which would be ours naturally and constantly if we lived rightly. No wonder we suffer from tubercle in these degenerate days of flesh and tea poisoning.

Even the diurnal variations in the rate of the capillary reflux, and the height of the blood-pressure are certain guides to causation, for they vary with the quantity of uric acid in the blood and often with that only. They can be made to vary in either direction at pleasure by altering the quantity of uric acid in the blood. Then by removing the uric acid factor, which we can do at pleasure, it is easy to see what other factors are left. We either control the whole of the abnormal condition of the circulation or we do not.

Thus, fever, apart from dyspnea, practically clears the blood of uric acid. It therefore quickens the capillary reflux and lowers the blood-pressure. Thus in fever we see exactly how much of a given blood-pressure has been due to resistance of tissues, thickened, or degenerate vessel walls, etc. Many years ago I remember being quite startled by a case of Bright's disease I was watching in the out-patient room of the Metropolitan Hospital. This patient was thought to have the high blood-pressure of chronic Bright's disease, with some thickening of the vessel walls. However, one morning she came with a temperature of 102° F., and the artery was soft, and could no longer be rolled under the finger; in fact, it was impossible to define the position of the vessel except by feeling for the pulsation within it. Here the whole trouble was the obstruction of the capillaries by uric acid, which the fever cleared up, and my belief in a thickened vessel wall was, in this case, mere scientific imagination. A really thickened wall, or a degenerate vessel, would not have disappeared in this way; thus fever enables us to gauge pretty accurately the vascular conditions with which we are dealing. A similar result can be produced by drugs, if they, like the fever, clear the blood of uric acid; thus we can in all conditions tell the approximate condition of the vessel walls by eliminating the uric acid factor and watching what is left.

I will now narrate a case which illustrates in a very definite way the great power of the circulation over nutrition and metabolism and thus makes evident the enormous influence which uric acid exercises in both physiology and pathology, in the production of what we have rashly called disease, which is more accurately "physiology disturbed by poison-taking." In this case the whole of the disturbance corresponded, as we shall see, with a rush of uric acid into the blood, which I have elsewhere spoken of as a uric acid storm. In this case the uric acid rushes into the blood as the result of quite ordinary causes, causes which under slightly different conditions might have produced the functional disturbances known as migraine or epilepsy, but none of these things have ever been diseases; they are symptoms of food-poisoning. Hence the way in which they occur together or in sequence in an almost indescribable variety of relations.

When the uric acid is in the blood it obstructs, as we have seen, the capillary circulation, this obstruction fatigues, overpowers, and finally dilates the heart and all the rest of the visible phenomena

are results of these effects. When the rush of uric acid expends itself, being largely cleared out by the kidneys, if we leave nature alone, or being cleared out by food and drugs, if we do not let it alone, the capillary circulation improves, the heart recovers itself and all is once more physiological.

The "disease," as we shall see, has been called "Purpura Rheumatica," but I merely regard it as a phase in the symptom complex of uric acid (food)-poisoning.

Florence H., aged 14, admitted under my care in the Royal Waterloo Hospital, February 23, 1912. Her notes are headed "Purpura Rheumatica." Result, "Cured." I agree neither with the diagnosis, as I have said, nor with the statement of result. The patient has gone home and doubtless in spite of all we can do or say and have done and said she is now exposed to the very conditions of food poisoning which produced her departure from physiology, and these will continue to produce the same or similar results in accordance with her age, work, exposure to weather and other conditions of home, school, or service life, so long as the poisons are continued or till they produce more serious and fatal trouble.

On admission she had hematuria, also bleeding from gums and nose. Three and a half years ago she first noticed red spots on her legs, and these have recurred from time to time but have been notably worse for the last six months since the monthly period established itself. She has pain and excessive loss at the periods which last five days. (See remarks on this point by Kenneth G. Haig, "Health Through Diet," Methuen, London, p. 118.) Her mother has rheumatism and morbus cordis. Patient had scarlet fever five years ago.

She is pale, temperature 99°, pulse 78, respiration 17. There is a marked petechial rash over face, chest, and abdomen, and it is very marked over both legs. There are also a few spots on the tongue. Heart's apex beat is in the 5th space in the left nipple line, no sign of valvular lesion. Lungs normal. Has pains in the knees and occasionally in the head. Some pain in the right iliac fossa hemorrhagic appendicitis(?). Urine on admission, 1024, acid, cloud of albumin, no sugar, many red cells, some pale cells, squamous and bladder epithelium, a few uric acid crystals, no casts.

February 26. Hematuria has ceased. February 28, all spots have disappeared. Temperature chiefly subnormal, only once touched 99° F. after the day of admission.

She was put on a light diet with fish, and given a mixture containing Calcii chlor. and Tr. Ferri Perchlor., ter p. c. Also Cactina one pillet ter.

On February 28, sugar 2 oz. and 1 oz. of dried milk were added. On March 1 the sugar was increased to 3 oz. For the above notes I am indebted to Dr. Mark Lindsay, the Senior R. M. O.

I first examined her on February 26, and found a pale, debilitated and teeth-marked tongue. A capillary reflux of 11, in spite of her having been for three days on the above named drugs. Blood decimal .85, temperature subnormal, transverse diameter of the heart (C. D.) 6¾ in. (normal 4½), *i.e.* more than two inches of enlargement. Liver dullness 4¼ in., showing considerable enlargement also. She had thus a capillary reflux which was from 3 to 4 (50 per cent.) slower than normal, there were also considerable debility and anemia and most important of all a dilated heart and a congested liver. She had considerable excess of uric acid in the blood and we know from the anemia that it had been there, off and on, for some time. On these conditions a more than usually severe uric acid storm had supervened, the heart failed under the accumulating misfortunes of anemia, bad nutrition, and obstructed capillaries, the circulation in some capillary districts stopped altogether, as we sometimes see it doing in the web of a frog's foot, the nutrition of the capillary walls suffered and, when the blood circulation was again turned on, various small leaks produced the hemorrhages we saw. The purpura was the result of a reflux slower than 11, which was doubtless present on admission, and this together with failing heart-power produced some defective vascular nutrition.

On February 29 the capillary reflux had quickened to 10; on March 11 the cardiac diameter had diminished to 6 in. (¾ in.) and the liver had gone down by the same amount to 3½ in. All signs of trouble had now been absent for twelve days.

On March 18 the capillary reflux had quickened to 9 and on the 25th to 8.5. The cardiac diameter had further diminished to 5½ in., an inch and a quarter less than when first measured, and the liver had diminished to 3¼ in. She was allowed to go home on the 29th, being cautioned as to the foods that were the cause of her trouble, and if she is able to avoid them in future she will hear no more of what has been called "rheumatism" or "purpura."

The most interesting fact in the history of this case is the increase of the trouble with the establishment of the monthly period. The attack which we witnessed followed close after such a period, being contemporaneous with what I have elsewhere spoken of as "post-menstrual collemia." The monthly period as we know accounts for the relative immunity of women from gout because it increases the elimination of uric acid. It will therefore increase their tendency to collemic circulation troubles, exactly in proportion as it diminishes their liability to local arthritic troubles (gout).

When in this case the monthly period induced increased collemia and increasing capillary obstruction it increased the work of the heart and at the same time diminished its nutrition, increasing also the general anemia and debility, and these eventually led up to the heart failure with dilatation, the congestion of the liver, the stasis in the capillaries of various parts leading up to rupture and leakage which accounted for the hematuria, epistaxis, and purpuric spots, and we found along with such phenomena all the physical conditions necessary for their production.

The treatment was to clear the blood of uric acid, to feed up and strengthen the heart, to diminish the anemia. We cleared the blood of uric acid by chloride of calcium, chloride of iron, and sugar. The sugar helping to produce this effect by diminishing the alkalinity of the blood, which is demonstrated by its increasing the acidity of the urine. We strengthened the heart by rest in bed, by cactina, and by increasing protein nourishment with dried milk, and as a result, while the heart and liver got smaller and the capillary reflux quickened towards normal, the whole thing cleared up. We had removed the cause and the effects followed it. Prevention in such cases is simple enough and consists in preventing subsequent excess of uric acid by ceasing to swallow it.

Given absence of excess of uric acid from the blood-stream the capillary vessels will not be obstructed, the heart and liver will not be enlarged and congested, the capillary circulation will not be

slowed, the vessel walls will not be badly nourished and become ruptured, hence there will be no hemorrhages. Those who live uric-acid-free have neither rheumatism nor purpora.

I may, perhaps, quote in further illustration of the same phenomena that tea is now regarded as a cause of neurasthenia. But neurasthenia, as I have elsewhere shown ("Uric Acid in the Clinic," p. 81 and elsewhere), is really "cardiasthenia," being dependent on a defective circulation in the great nerve centers due to cardiac debility. We have just seen how a uric acid storm brought about cardiac debility in the case of Florence H., and the rest follows in simple sequence, for thein is a xanthin compound and tea thus introduces xanthin or uric acid into the body in large quantities, from 3 or 4 grs. per day, (the average consumption of tea per head of population) up to 20 or even 30 grs. per day in some cases; so that there is little cause to wonder at the increasing prevalence of neurasthenia even from this one source of uric acid poisoning.

Again, in the neurasthenia produced by tea and uric acid from other sources, there is often present a symptom of great interest, namely, a feeling of sinking emptiness commonly referred to the epigastrium and accompanied or followed by shortness of temper. Now the causation of these symptoms is very simple, once we understand the mechanism of a uric acid storm as seen in the case of Florence H. The feeling of sinking and emptiness means that owing to gastroduodenal congestion (the causation of which has been given above) the functions of digestion and absorption have for a time been brought to a standstill and so there is no longer any passage of fresh proteid from the digestive organs into the blood. The blood is short of the only substance (proteid) which makes fresh force available. (I have given several instances of this in "Uric Acid"; see also under the causation of force in "Diet and Food.") We shall also find, if we examine the urine, that at the same moment as this feeling of shortage of force appears, any drug which may be lying in the stomach has ceased to pass into the urine, which no longer gives the chemical reactions due to it, but the reaction will return if the circulation is restored. The circulation was bad first of all on account of the collemic obstruction of capillaries, but we now have another factor added to this, namely, deficient heart and muscle power from want of protein to stoke the engines. The circulation throughout the body at once becomes still worse, and the now very defective circulation in the brain causes irritability and bad temper. Hence the saying "A hungry man is an angry man," which applies specially to the hungry poison-taker and not to the uric-acid-free. The remedy is to clear the blood of uric acid and then digestion is resumed, fresh proteids are absorbed, the feelings of powerlessness and bad temper vanish, and the chemical reaction appears once more in the urine. Attacks of migraine and epilepsy furnish, if examined, a complete series of parallel phenomena, for they also, like the sufferings of Florence H., are results of a collemic storm; and an epileptic attack is often a result of an intracranial circulatory condition which differs merely in degree from that producing bad temper.

While we have these facts in mind, it is easy to explain a point recently brought to my notice by a patient residing in South Africa who had been told by his local doctor that a glycosuria from which he suffered was due to eating too much fruit. I have no doubt that his doctor was perfectly right and had probably seen other cases of glycosuria produced in the same way. When I saw this patient he had got rid of his glycosuria but still had a very defective circulation due to excess of uric acid in his blood. From these facts I inferred that at the time of the glycosuria the circulation was decidedly more defective, just as the circulation of Florence H. was worse at the onset of her purpura and hemorrhages than when these phenomena had ceased. This man was quite wrong in eating fruit in the way he did, for he took it along with beef, mutton, pork, tea, and coffee; if he had taken it only with nuts and left the rest out we may suspect that he would never have had any glycosuria. But when he allowed the acids of the fruit to cause considerable retention in his body of the poisonous waste products contained in flesh, tea, coffee, etc., he laid up a store of trouble for himsef in the future. When at some later date the uric acid so stored rushed into his blood it produced, as we saw it doing in the case of Florence H., congestion of stomach, duodenum, pancreas, and liver, and thus a temporary glycosuria was easily accounted for. When I saw him the worst of the storm had passed over and the circulation, though still abnormal, was not nearly so bad as it had been, and so the glycosuria had departed.

In collemia the circulation, and consequently the metabolism of the whole body, is slowed and obstructed, and these conditions will obviously be greatly increased the moment we get heart failure added to the collemia. Then this collemia and obstruction will continue till retention has been reestablished or till the whole of the accumulated uric acid has been cleared out of the body. Hence there is only one way out of collemia and its troubles and that is to remove all accumulations and prevent their reforming by ceasing to swallow the abovenamed foods. For all retention must mean collemia at some future time; nevertheless in Bright's disease, for instance, we have sometimes to cure by retention, for when the stores of urate in the body are large an attempt to cure by elimination would mean an increase of collemia sufficient perhaps to stop all metabolism and destroy life. Now the question arises: What happens in Bright's disease when we cure it by retention or when nature cures it by intercurrent fever? The retention clears the blood of uric acid and at once the excretion of urea rises by leaps and bounds, the water passes freely through the kidneys and dropsy vanishes, food is completely absorbed and metabolized, and the heart and muscular tissues are properly nourished, the fires of metabolism burn up and the uric acid is kept out of the blood for days, weeks, months, even years, and the Bright's disease may be cured. What then happens to the uric acid accumulated by the fever or the retentives? The improvement of metabolism keeps up the retention and a store capable of producing future damage is produced once more. Yes, if the patient goes back to ordinary (poisonous) diet, this is so, but if he lives uric-acid-free there will be a slow solution and removal of the stored uric acid, which passing through the blood only in small amounts does little or no damage, and then in the course of years the body gets free from accumulations and all goes well.

We see then that albuminuria and glycosuria are both failures of metabolism due to defective circulation. This explains why the two great factors of defective circulation, viz., excess of uric acid in the

blood and deficient heart power, are so constantly found in association with them and why they parallel each other in so many directions and bear identical relations to pregnancy, for instance, which puts increased work on the heart, and relatively weakens it, and why both clear up and disappear when the time of heart stress comes to an end with delivery. The one thing obvious on the surface in albuminuria, glycosuria, Bright's disease, and diabetes is the very slow capillary circulation in the skin, and this is accompanied by signs of weak heart and subnormal temperature, the great clinical sign of defective combustion.

This causation also enables us to explain the relation of these metabolic failures to the natural history of bodily development, and the stages of life; but for full details of this matter I must refer to "Uric Acid," p. 236, and will merely point out here the well-known fact that both albuminuria and glycosuria are most commonly met with in the decline of life, in what I have called the second collemic stage, when all the uric acid accumulated in the second retention stage (prime of life) rushes into the blood, blocking and disordering the whole physiology of life. First obstructing the capillary circulation thus at one and the same time both overworking the heart and diminishing its nutrition, and finally causing congestion and disordered metabolism in all the great metabolic tissues and glands of the body, resulting in general mental and bodily depression, fatigue, and lethargy. We can now see that none of this is, or has ever been disease; it represents merely the primary secondary and tertiary effects of chronic food-poisoning.

Collemia is proportional to the uric acid available, that is to say, it is proportional to introduction plus retention. The slowing of the capillary reflux by a given quantity of urate is proportional to the weakness of the heart. As the heart gets weaker and less well nourished a given quantity of urate produces ever worse and worse results as regards metabolism and combustion, and, as a matter of fact, even the most severe collemia does not produce marked albuminuria or glycosuria unless the heart is weak or becoming badly nourished.

We can see also that if the heart is weak the circulation and metabolism of the entire body will be more adversely affected by smaller quantities of uric acid than when the heart is strong, and this whether the weakness results from congenital structural defect, from mere defective use and poor muscle development, or from valvular or pericardial distortion, the result of that other phase of food-poisoning, which we have called rheumatism.

Similarly when the lungs have been damaged by such things as asthma, bronchitis, emphysema, pneumonia, or pleurisy, the bad effects of a given quantity of uric acid on metabolism and combustion will be similarly increased. Now this metabolism entails the change of certain chemical compounds in the food into other compounds in the tissues and these again into still other compounds in the excreta: the force, heat, motion, power, which make up life being got from these compounds at every change. The chief substance in the food which produces power is proteid and its end product in the excreta is urea, hence when anything hinders metabolism some proteid remains incompletely metabolized and force and urea (its end products) are not obtained or at least not in their right quantity. If this process stops at a certain stage a wrong kind of albumin is left stranded in the blood, a diffusible in place of a non-diffusible albumin; then this diffusible albumin passes into the urine as well as into various other excretions and this has been looked upon as the first stage of Bright's disease. But we can now see that it was by no means the first stage of the metabolic disturbance, and on tracing this back to its real cause we find that there is not and has never been such a thing as Bright's disease, at least as a separate pathological entity, for the whole trouble originated in the swallowing of poison along with food.

If we define disease as discomfort or a lapse from health, this has undoubtedly been produced at various stages in the course of food poisoning. But we have always been careful to say that the coma of opium or the rash of belladonna poisoning, though undoubted lapses from health are not diseases but toxic states, and logically we cannot continue to call Bright's disease and diabetes pathological entities once we know that they are but stages in poisoning by foods containing uric acid and xanthin. We can now see the way in which the defective circulation of collemia exposes the lungs to parasitic invasion and that this condition will become still more favorable to parasites if heart failure is added to collemia. The conditions that favor the onset of phthisis are therefore the exact parallel of those that produce albuminuria or glycosuria. Microbic invasion is greatly favored by certain stages of food poisoning and is hindered by its absence.

There are only two causes of defective metabolism or combustion in the body, and the one leads on inevitably to the other. The first and therefore more important is the obstruction of the capillary circulation throughout the body by uric acid in the blood stream. Then, as I showed many years ago, every excess of uric acid in the blood lowers the excretion of urea in the urine because it interferes with the metabolism of albumins and thus diminishes the formation of urea. The other great factor which interferes with tissue circulation and so with tissue metabolism is a weak and diseased heart; and this may be either mere muscle weakness (just as a gymnast's biceps is weak when he has not used his arm for six months), or congenital structural deformity, or rheumatic lesion of the valves or pericardium.

Now chronic excess of uric acid in the blood leads to defective nutrition of the heart muscle, and, at the same time, increases its work. And these two effects being continued, must inevitably lead to dilatation and progressive loss of power in the heart muscle; and thus these two factors in combination lie at the root of that defective metabolism of proteins which has been called Bright's disease as well as of all defective metabolism.

It is thus clear that Bright's disease originates in excess of uric acid in the blood, in other words, it is an effect of uric acid poisoning, just as coma is a result of opium poisoning. It was merely called a disease by Bright and others who did not understand its origin.

Then the defective metabolism which affects protein may also diminish the combustion of sugar, and thus we get excess of sugar left in tissues, blood, and urine. And this again is no more a disease than is Bright's disease, it is a mere result of food poisoning by uric acid. The same is true of the defective combustion of fat (obesity). All defective combustion, except that due to deformity of heart or lungs, is a mere phase in food poisoning; none of these things are diseases, they are results of poison-

ing by excess of one single substance—uric acid.

Now nothing is ever gained by calling things by their wrong names or by attributing them to causes which do not exist, for if knowledge is power, ignorance must be lack of power, and so it proves in this case. Once we know that these things with their many names and supposed numerous causes are not inevitable and incurable diseases, but mere results of poisoning we come at once into possession of a power previously unknown which embraces prevention and cure. You have only got to leave out the uric acid to prevent their appearing. Further if the poisoning has not been so long continued as to produce serious structural change, leaving out the poison will bring about cure. But this is not cure of disease, we have removed the poison and the symptoms of poisoning cease.

If the kidney has become a fibrous nodule its wonderful structure cannot be replaced. If the arteries have become as hard as pipe stems they cannot be made young and elastic again. You do not cure Bright's disease, for it never existed, but you can stop uric acid poisoning at any stage it may have got to short of actual and immediate danger to life.

Practically the rate of the capillary circulation together with the condition of the heart and kidneys are the guides to the stage of poisoning that has been arrived at, as well as to what you can do in the way of repair and recuperation by shutting out the poisons. Precisely the same applies to glycosuria and diabetes, also to obesity and all defects of combustion and metabolism due to food poisoning; the circulation is the guide both to what has been done and to what can be done.

When you see a very defective capillary circulation the first thing to do is to estimate the uric acid in the blood, if this does not seem to be enough to account for all the defect present you will suspect heart or lung disease as a complication and the other circulation measurements will confirm this and tell the relative importance of each factor. You will next make out the condition of the heart, of its muscle and its valves, and then note the effects of these conditions on the blood and blood-vessels and beyond these on the great organs of metabolism (the skin, the muscles, the brain, the nerves, liver, stomach, duodenum, pancreas, spleen, intestines, spinal cord) and their functions, and, when you have further examined the excretion of the kidneys and its relation to the food taken, you can form a very fair estimate of the stage of poisoning arrived at and how far it may be possible by removing all further poison from the food to produce a more or less normal body. But even our estimate of normality has been debased by our lamentable experiences of chronic poisoning; the debased thing has come to be regarded as the highest standard. It will take two or three generations of growth and development on the normal food of man to show us what we have lost. The coming generations who live to see it will be fairly astonished at it, they will then see that life is not quite such a simple process or so much under their control as they had imagined.

When you find that the heart muscle is weak, perhaps becoming fatty, the aorta dilated, the arteries rough, tortuous, and pulsating visibly like snakes under the skin, the lungs emphysematous, the bronchi thickened, the liver fibrous from oft repeated chronic congestion, the stomach, duodenum, and pancreas tending in the same direction with chronic congestion and frequent catarrhal exacerbations, when intestines are catarrhal and partially atrophied, the kidneys fibrous, and the urine of low specific gravity, when there has been a cerebral hemorrhage and mind and memory are impaired, when dilated vessels stand visible on the skin everywhere, and large veins in knots and nodules are on view all over the lower extremities, and when the whole skin is discolored, shriveled, and dry, you know that food poisoning has done its worst, and that the body is only a melancholy remains of what it might have been. There is here all the difference between life and death, between happiness and misery, between mind and its absence, between animal and man.

Writers on diabetes have frequently acknowledged that its problems are still obscure, and Frerichs has named it the Sphinx of medicine. ("Uric Acid," p. 652.) But obscurity is simply another word for ignorance of the real cause, and if I am right in saying that diabetes also is not a disease and has never been one but represents only one stage or one side issue in the course of chronic food poisoning, we may find that this pathology, if more correct, will throw fresh light on some of its problems.

I have elsewhere pointed out the way in which the relationship of glycosuria to collemia enables us to explain the well known fact that a quantity of bread or fruit which at once produces an increased excretion of glucose if given in the morning hours, can be given in the evening hours without producing any bad effect. (See "Uric Acid," Ed. VII, p. 633.) I have there also pointed out that the explanation of these facts which is commonly given, viz., that starch and sugar given when the stomach and intestines are empty and free from work pass more quickly into the blood and urine in the morning than under the opposite conditions in the evening is not correct. And further investigation shows this to be but one instance of a general law, that products of incomplete combustion move together and in the opposite direction to that of the products of complete combustion. Now urea is a product of complete combustion, as sugar and albumin are products of incomplete; therefore when sugar and albumin rise or fall, urea will move in the opposite direction. When a mixed meal is given in the morning to a patient who suffers from both albuminuria and glycosuria the excretion of albumin and of glucose will rise more quickly than in the evening, but the urea will rise more slowly; but if the commonly given explanation were true that stomach and intestines are empty and metabolism free they should *all* rise more quickly in the morning hours. On the other hand my general law explains all the facts completely, products of incomplete combustion rise more quickly in the morning because combustion is then more incomplete, owing to defective circulation which is obvious on the surface of the body, and for the same reason urea rises more slowly; in the evening products of incomplete combustion rise more slowly because circulation is obviously quicker and combustion more complete, hence urea rises more quickly. The rise of sugar in the morning hours after a dose of fruit which will produce no glycosuria in the evening, is not due to increased absorption, but to diminished combustion, and exactly the same applies to albuminuria. Albumin, *when it is a product of defective combustion*, rises more quickly in the morning, and this fact can, as I have shown, be used to distinguish between albuminuria due to that defective combustion from food poison-

ing, which has wrongly been called Bright's disease, and that due to a mechanical cause, *e.g.* oxaluria. Albuminuria due to oxalates is at its worst in the night hours when the acidity of the urine is at its highest and the precipitation of oxalates greatest; albuminuria due to defective combustion is at its worst at the opposite pole of the day, the morning hours; and you can prove this in the same way that you can in the case of metabolic glycosuria, give some extra albumin in the morning and the albumin in the urine will increase, while an extra dose of albumin will produce no effect on albuminuria due to oxalates or any other mechanical cause.

We have also a complete explanation of the fact that fever, when it clears the blood of uric acid and so quickens the capillary circulation throughout the body, diminishes the excretion of sugar and albumin, but increases that of urea, while with subnormal temperature go collemia and slow capillary circulation, a large excretion of sugar or albumin, and a low excretion of urea; thus the subnormal temperature itself is always a sign of defective combustion. In fact sugar, albumin, and urea, the correlative of albumin, rise and fall all day long with the quantity of uric acid in the blood, and when fever does not clear the blood of uric acid, when, as in pneumonia, lack of oxygen prevents increase of oxidation and rise of acidity, then also does fever fail to diminish albuminuria and glycosuria and to increase urea. And if you examine the blood in pneumonia or other febrile conditions accompanied by dyspnea you will find that the fever has failed to clear the blood of uric acid and all the other metabolic failures are the result of this. Thus the rate of the capillary circulation is an absolutely complete index of the quantity of uric acid in the blood, and the temperature and all metabolic phenomena are controlled by this.

Further we shall see presently that most of the well attested causes of glycosuria and diabetes have one thing in common, they all slow the capillary circulation, and they do this either by increasing the uric acid in the blood or by weakening the driving power of the heart. For it is obvious that the weaker, or less effective, the heart power, the greater will be the effect on the circulation of a given quantity of uric acid.

For instance, there are quite a number of drugs that are known to produce glycosuria, and these all belong to the group of what I have called retentives, *i.e.* they increase the uric acid in the body by causing it to accumulate or be retained. Later on, when this accumulated uric acid rushes into the blood stream, severe collemia is produced and very defective capillary circulation results for a time. This is illustrated for instance in the common causation of migraine (the uric acid headache); a man exposes himself to cold or takes some excess of acid wine or of fruit out of season and thus accumulates some 8 or 10 grs. of uric acid, and some days later, when this gets a chance of passing into the blood, he gets a high-blood-pressure headache, and this may be accompanied, as we know, by an albuminuria or a glycosuria or both. Now among the drugs known to cause glycosuria are morphine, perchloride of mercury, uranium salts, nitrite of amyl, copaiba, etc., and each of these will be found mentioned in "Uric Acid" as a powerful retentive. They would all equally cause bilious attacks, "chill to the liver," headache, epilepsy, mental depression, insomnia, or any other of the variety of names with which medical writers have dignified food poisoning and its phases, the whole phenomena of "the uric acid storm" of which, as we now know, albuminuria or glycosuria are but some of the final results. Then, as we have seen in the case of Florence H., they all upset the circulation in the stomach, liver, duodenum, pancreas, kidneys, and skin, in fact the circulation controlling the entire metabolism of the body, and the effects on albumin, sugar, and urea are results of this.

Then asphyxia increases the uric acid in the blood, and dyspnea is, as we have just seen, the one thing which prevents fever from clearing the blood of uric acid and thus quickening the metabolism of the body. It is not, therefore, remarkable that asphyxia, like other factors which increase the uric acid in the blood stream, should produce glycosuria.

Again, such things as mental shocks and nervous strains prove on analysis to be really heart strains; all are now familiar with the fact that blood pressure at once runs up under conditions of fear and excitement, thus tiring a heart perhaps already weakened by a long struggle against collemia and defective capillary circulation. Continued insomnia again is a fertile cause of deficient heart nourishment and increased heart strain, and the worse the heart gets, the worse also becomes the insomnia. We have here a vicious circle which must in the nature of things increase as long as plenty of uric acid is available. It is not, therefore, extraordinary that mental shock, which means heart strain, should increase the effects of collemia in the food-poisoned and thus take a hand in the production of glycosuria and diabetes. Many diseases of the nervous system, owing to their secondary effects on the heart and circulation, will obviously act in the same way.

The effects of fevers we have already spoken of in explaining the relation of glycosuria to time of day, and they obviously act just like the retentive drugs mentioned above. I have elsewhere gone at length into the effects of pneumonia, scarlet fever, measles, and malaria in this respect, and we can now easily see that they produce glycosuria through their effects on collemia.

Nor is it at all remarkable that glycosuria should accompany some diseases of the liver and pancreas. The fact that it does not constantly accompany all such diseased conditions shows that the relation is an indirect one and due to that factor which is common to glycosuria and to some diseases of the liver and pancreas, but not to all, viz., collemia. Primary carcinoma of the pancreas, for instance, may not be accompanied by glycosuria; it will be accompanied by it if it produces severe collemia and very defective combustion, but this obviously depends on factors outside the pancreas, viz., the quantity of uric acid available in the body, and the strength of the heart. Thus in some cases of primary pancreatic disease we get glycosuria and in some not, and this suffices to explain all the facts in front of us. On the other hand when pancreatic disease is due to collemia, and is but a part of similar disease affecting at the same time and in the same way stomach, liver, and duodenum, we may get glycosuria with the pancreatic changes because the glycosuria is a co-result of the collemia.

The effects of gastrointestinal troubles are again most interesting for there is nothing which is more certain to cause collemia in the food-poisoned than defective absorption or metabolism of food. It increases the alkalinity of the blood, and at once all the uric acid in the body available for solution rushes into the circulation. There is thus no more common cause of mental depression or insanity than the

collemia precipitated by dyspepsia. The poor food-poisoned one is here in the grip of a vicious circle, for collemia, as we have seen, produces dyspepsia and dyspepsia in turn increases collemia, and after several downward turns of this kind, as the heart, from continued over-work and poor nourishment by defective blood, gets weaker, the whole metabolism of the body gets steadily worse till albumin or sugar or the two alternately or together are present in the urine.

Pregnancy again, by overworking and straining the heart, will obviously increase the bad effects of collemia, and will thus account for an albuminuria or glycosuria in the food-poisoned. The first incident in the pregnancy is perhaps some little dyspepsia, and this introduces the above described vicious circle, sometimes with dire effects. But, as we now know, pregnancy in those who are not food-poisoned is altogether a different matter, and puts far less strain on the physiology of the body. (See "Health Through Diet," p. 119.)

I have often been asked why, as they are both failures of combustion due to the same cause (food-poisoning), diabetes should be harder to cure than Bright's disease, and why I have recorded a good many cures of the latter and few or none of the former? But when we view these processes in their real light, as stages in a progressive process of food-poisoning, the answer to this question is not, I think, very difficult. For in diabetes you have not only to deal, as in Bright's disease, with great debility of the heart, but there is present a condition which renders any improvement of its nutrition practically impossible, and we equally fail in Bright's disease where the heart condition has gone beyond that which it is possible to repair.

Now in diabetes we have an important added cause of deficient metabolism and defective nutrition which will, doubtless, affect the muscular nutrition in general and that of the heart in particular, viz., the change which sugar produces in the specific gravity of the blood, a change which cannot fail to interfere with the normal interchange of nourishment and waste products between the blood and the tissues.

In Bright's disease it is often possible to improve the nutrition of the heart muscle and thus obtain more driving power to counteract part of the defective capillary circulation, but in diabetes this is not so, it may be impossible to help the heart except by clearing the blood of sugar, which cannot always be done. Hence the improvement of metabolism that follows the reduction of sugar to its lowest limits by diet, and where sugar can by any means be entirely got rid of cure is possible, for the heart can now be strengthened and metabolism will improve to a corresponding extent. Till I understood this I was unable to account for the steady and continuous failure of heart tonics in diabetes. They show a precisely similar failure in Bright's disease, if we fail to get enough protein into the circulation to nourish the heart muscle. In this way glycemia is more deadly than heteroalbuminemia; and diabetes, as soon as the blood can no longer be cleared of sugar, is of necessity fatal, for the heart-failure factor and its cause cannot be removed, and generally the collemia factor cannot be so either. The obvious treatment is to clear the blood of sugar and uric acid and to strengthen the heart to the utmost of our power at one and the same time, and, if we can succeed, we shall save life; but in Bright's disease we have only two of these things to do to clear up the collemia and strengthen the heart and we are much more likely to succeed. In this case the foreign albumin in the blood matters but little, it may not interfere with the nutrition of the heart at all. Sugar on the other hand is quite a different matter, it goes to the root of nutrition and blocks all its processes. In the early stages it is possible to clear the blood of sugar, it is, therefore, possible to improve nutrition and the driving power of the heart and thus to diminish and eventually to remove the power of collemia for evil. But later on, as the heart gets weaker, glycemia will increase, and when it becomes impossible to aid the heart's nutrition owing to this increase, the vicious circle is closed against us and the power of collemia must continue uncontrolled and uncontrollable. Our only chance now is to clear the blood and body from collemia, and this is, no doubt, the way in which the salicylates, which I have made so much use of in diabetes, sometimes produce a good result. But only too often their action is hindered by increasing heart weakness, which the collemia they produce in the process of clearing urates out of the body does nothing to improve. Indeed in the cardiac debility of the old or under-fed the collemia of salicylates is only too likely to cause dangerous dilatation of the heart; and the diabetic is in much the same position. Make the capillary reflux normal and you have set free the metabolism of the body, and sugar or albumin will soon disappear from the urine. If you fail to do it you now know why you fail, and you also know, in the case of diabetes, why and to what extent the failure is final. It is similarly final in Bright's disease, once the heart is beyond repair, but heteroalbuminemia is not so great a hindrance to this repair as glycemia, hence the difference between them.

Asphyxia, of course, increases collemia and generally also directly diminishes the power of the heart by obstructing the pulmonary circulation. Thus fever and asphyxia pull in opposite directions and have to fight it out till the strongest wins; if the blood can be cleared of uric acid and the fever wins up goes the metabolism of the body and urea rises as a result of this, if it cannot be cleared the asphyxia wins and the metabolism of the body cannot be righted unless the cause of the asphyxia is removed. Every cause of asphyxia is therefore a possible cause of glycosuria or albuminuria and of these the glycosuria is the more difficult to cure for the reasons given above.

Fatigue, of course, increases the power of collemia in two ways, it increases the uric acid in the blood by increasing its solvent power, and it diminishes the power of the heart by diminishing its reserves, its muscle nutrition, and by hindering its capillary and general circulation. Then we know that fatigue will cause albuminuria in exactly the same way as it causes glycosuria; boys who faint at the end of a race are certain to be found with dilated hearts and probably with albuminuria also. Boys on natural diet who have no collemia from food-poisoning do not faint in this way and never have what is called "a bad time" nor do they show a dilated heart nor albuminuria, for the cause of such albuminuria is not athletic strain, a thing inevitable in the nature of things, but strain of a food-poisoned body by exercise which would not strain a normal one.

Again we know that a man who may be able to take sugar freely without showing any glycosuria when well, may be unable to do this when he suf-

fers from colic due to lead and other causes. But colic in any form means gastrointestinal derangement, deficient absorption of food, and increasing collemia, and increasing collemia diminishes a man's power of metabolizing sugar. Then in most cases of colic that last long, the collemia is soon backed up by the other great factor in defective metabolism, *i.e.* heart failure. Some hearts will fight against collemia for years before they give in, hence the very high blood-pressures we sometimes find in such cases; in others they seem to be overpowered in the first rush of collemia, and either never get time to hypertrophy or have not the means at their disposal of making any effective increase of power at the moment it is wanted. I mention in "Uric Acid in the Clinic," p. 87, a case in which the heart very nearly succumbed to the first rush of collemia, but nine years later had become a very powerful organ with correspondingly high blood-pressure. This was because its owner did not understand the mechanism of his trouble and so did not take the measures necessary to shut out the poisons from his food.

The relation of glycosuria to the administration of sugar on an empty stomach (*i.e.* apart from the effect of morning hours previously referred to), is again a mere matter of collemia or its absence. In the saying previously mentioned "a hungry man is an angry man" we have the key to the causation of such a glycosuria, for in the food-poisoned the hungry man is the collemic man, and the collemic man with correspondingly defective brain circulation is the angry man. Now this same defective circulation throughout the body diminishes power of metabolizing sugar completely. Give sugar before a meal to such a man and he may show some glycosuria, and yet precisely the same amount of sugar given after his meal will not cause any sugar to pass into his urine, and you will find that with this absence of glycosuria there is also good temper, he is placid and smiling and cannot easily be made angry. The explanation of this again is quite simple, and, if you had only been measuring the rate of the capillary circulation under these two conditions, you would have seen the reason of it all. Or, if you watch the excretion of urea and the quantity of uric acid in the blood, you will again see what happens. About an hour after the first mouthfuls of the meal the urea begins to rise, and with urea rises also the acidity of the urine, and the rise of acidity clears up the collemia, the circulation in the brain improves, and the angry man becomes peaceful, the same improved circulation improves his metabolism of sugar, and so there is now no excretion of glucose. This change from bad temper to happiness is in many people quite remarkable and it always corresponds to this rise of urea and acidity which takes place from forty to sixty minutes after the beginning of a meal; but the unfortunate dyspeptic in whom this rise may be more or less delayed or diminished remains morose. In all such cases you have merely to watch the capillary circulation to see exactly what is taking place. We here come in sight of the probable explanation of the morning nausea and vomiting of pregnancy, and of the reason why some early food may cure it.

Pregnancy is a time of retention and consequently the morning collemia will be rather severe, this causes some gastroduodenal congestion with tendency to nausea and vomiting. Then the digestion of food will put an end to the collemia and congestion in 40 to 60 minutes, as we see from the above considerations. This is but a special instance of what is known in Scotland as "piecey disease," *i.e.* people who are always in want of a bit (piece) of food and so eat very often, the reason being that they have gastric irritability and congestion which the food relieves for a time. They have no real hunger, but they want relief from a pathological condition. (See my paper on "Gout of the Intestines," MEDICAL RECORD, Oct. 12, 1912, under "hunger pain".)

The well known tendency of all these defects of metabolism and combustion to appear in middle and later life is again merely the expression of their relation to long continued food poisoning with the excess of uric acid which has accumulated in the body and the progressive weakening of the muscles, especially that of the heart, which places the capillary circulation and so the metabolism of the body, ever more and more at the mercy of the obstructing uric acid.

The classical bilious attack is the center and the key of the whole phenomenon, and both albuminuria and glycosuria first come temporarily in such an attack, and later, with increasing collemia and diminishing heart power, temporary becomes chronic, albuminuria becomes Bright's disease, and glycosuria passes into diabetes; but here again the capillary circulation tells us exactly what is taking place and why. Obviously all shocks and bodily injuries in the food-poisoned mean collemia and also often heart fatigue and debility, though there is no greater cause of heart failure than collemia itself. Hence those who are not food-poisoned recover from injury or operation with what appears by comparison to be marvelous ease and rapidity.

The relation of these metabolic troubles to fibroses such as fibrosis of the pancreas in the case of glycosuria, is merely their relation to chronic and repeated collemia, for not merely the pancreas but the liver and all the neighboring organs are similarly fibrosed from exposure for years to defective circulation and recurring congestion. Relapse of collemia with any shock that debilitates and weakens the heart will mean relapse of a glycosuria or diabetes and with this may often be found offensive stools like those of the common bilious attack, and these with the passage of undigested fat are but further evidence of a blocked and congested circulation in stomach, duodenum, liver, and pancreas, while jaundice, when it occurs with glycosuria or diabetes, is but one more result of similar conditions. But collemia and defective capillary circulation is the *causa causans*, and we must not attribute to local conditions in one particular organ that which is the result of defective combustion throughout the body.

Then again generalized fibrosis is but one more result of chronic collemia and congestion with defective tissue metabolism and nutrition, though localized fibrous nodules and adhesions in the organs of the pelvis or abdomen are, like the fibrous nodules so common on the fingers, mere results of urate irritation. But no doubt in many of these organs we get mixed conditions, for direct uratic irritation alternates from time to time with collemic congestion. Thus gastrointestinal catarrh and colitis (retention diseases) alternate with the congestion of the collemia that intervenes between the attacks, thus the ultimate condition of the organs concerned is the result of both processes acting in sequence. It is therefore little wonder that these conditions are

sometimes found in association with those defective combustions of sugar or albumin which we have wrongly called Bright's disease or diabetes. Many cases illustrating these points and demonstrating the utter confusion in which we are landed by the attempt to break up one continuous process of food poisoning into various so-called "diseases" merely because we constantly see it at different stages, will be found in "Uric Acid in the Clinic."

Diarrhea again, is often a mere result of gastro-intestinal congestion, as for instance the congestion produced by collemia when it becomes associated with cardiac failure, and with this also we may naturally get either a glycosuria or an albuminuria.

A glycosuria following scarlet fever or measles or malaria is again quite simple, it is a mere phenomenon of postfebrile collemia, especially if this is associated with some cardiac debility of which the precedent fever is an efficient cause. It will often disappear after 7 or 8 days as the postfebrile collemia generally only lasts about as long as the fever which produced it, and the glycosuria or albuminuria will depart with it.

In the same way administration of uric acid under certain conditions will produce collemia and cause a bias in the direction of cardiac debility, and may thus bring about albuminuria or glycosuria. Under other conditions it will act as a stimulant, clear up collemia, and remove these troubles. The result depends entirely on the power that the blood has, in a given case and at a given time, to hold uric acid in solution and so produce collemia, or to throw it out of solution and so produce gout. Even time of day has a great determining effect in such a case, a dose of uric acid in the morning will get into solution in the blood, increase collemia, and thus aid the production of any impending collemic troubles, but exactly the same dose given in the evening may clear the blood of uric acid stop collemia, but give rise to troubles of the retentive series.

It has been known for many years that to administer uric acid or urates may cause a rise in the excretion of urea in the urine, and it was at one time concluded that this rise of urea represented the administered uric acid which had been converted into urea by the metabolism of the body. This result also was looked upon as further evidence in favor of the fashionable fad of the day that the body could thus undoubtedly convert uric acid into urea, so that those who suffered from excess of uric acid did so only because they had less than the normal power of converting it into urea. That, in fact, for a normal person administration of uric acid would do no harm and would not increase the quantity of that substance in the body.

But unfortunately for this theory experimenters soon discovered that every acid administered caused a rise of urea, and the same result followed on the administration of such things as sugar and of sulphuric acid which contained no nitrogen, so that the rise of urea following the administration of uric acid did not necessarily come from the nitrogen of the uric acid, hence the fact that a rise of urea followed the administration of uric acid was no proof that uric acid had been converted into urea. Further experiment then showed that if salicylic acid (a solvent) is administered with uric acid, the whole of the uric acid is excreted day by day in the urine in the exact quantity swallowed. This showed that the uric acid swallowed was not converted into urea, but was merely retained in the liver, from which a solvent could remove it at any time. It proved also that administration of uric acid raised urea just as administration of sulphuric acid raised it by freeing the metabolism of the body from collemia.

I also demonstrated years ago in animals that injection of uric acid into the blood stream did not increase the amount in the blood and urine, it was all caught up and retained in the liver, the quantity in the blood being actually diminished.

We learn from this that to administer uric acid when it can be dissolved in the blood, *i.e.* when the blood can take up more than it already contains, increases collemia and the excretion of uric acid in the urine; but to administer it when the blood cannot dissolve any more leads to its being thrown out of solution and retained in the liver, the blood is thus more or less cleared and the excretion in the urine diminished. A small dose of uric acid is therefore more likely to remain in solution and cause collemia, and a large dose is more likely to cause retention with clearance of the blood and accumulation in the liver. Thus the solvent powers of the blood control the effects we shall produce, and by giving alkalies or salicylates we can ensure the passage of the uric acid through the body exactly as we administer it. We now know also quite well that to keep uric acid out of the food controls completely the quantity available in the body, or the uric-acid-free diet would produce no good effects.

In this way not a few glandular preparations, *e.g.* thyroid, will produce quite different effects in cases which on the surface appear to be similar. Many of these glandular substances either themselves contain uric acid or xanthin, or substances such as ammonia or urea which affect the solubility of the uric acid already in the circulation of the patient to whom they are administered. A careful measurement of the condition of the blood and its circulation will furnish the reasons for their various actions under varying conditions affecting solubility. In other conditions again, *e.g.* myxedema and obesity, measurement of the circulation will explain the similar relation of these disturbances to albuminuria or glycosuria. The same observations will tell us why either glycosuria or albuminuria may come with a certain stage of pregnancy and depart after delivery, and in other cases why they are and remain absent. Everything depends on the effects of pregnancy on the heart condition, and so on the general circulation of the body, its digestion and metabolism. Everything that slows the capillary circulation increases the tendency to albuminuria or glycosuria because these are defects in the combustion of these and other substances in the metabolism. Everything that quickens capillary circulation diminishes the tendency to them. Probably the internal secretions of various glands have no effect on these errors of metabolism except in so far as they directly or indirectly increase or diminish collemia, or increase or diminish its effects by diminishing or increasing the power of the heart.

The relation of glycosuria to pelvic disease in females is again quite simple, for everything that increases gastrointestinal irregularity or dyspepsia will increase collemia in the food-poisoned, it will also slowly diminish heart power, thus controlling or importantly influencing the two great factors in the causation of glycosuria. And obviously the operative removal of such tumor or source of irritation will cure by removing the source of abdominal disturbance. The same may apply to constipation or colitis and so to the effect of removal or short circuiting of the colon.

Watch the circulation and you will not need to consider very much the condition of special organs which is very often a mere co-result of the general conditions; if pancreatic disease or irritation causes glycosuria it very often does so merely in the same way as the pelvic tumor mentioned above by upsetting gastrointestinal digestion and so producing collemia and defective metabolism.

Again diet restriction in glycosuria has much more effect than in albuminuria, for in the former it may stop one of the causes of cardiac debility, *i.e.* one of the main factors in causation. Albuminuria on the other hand is not cured by diminished protein, as this has the most undesirable effect of increasing cardiac debility. When it is possible to put the circulation right it is possible to cure any of these errors of metabolism, but it cannot be put right in glycosuria without removing the sugar. If the heart is very strong, *i.e.* if the error of metabolism was entirely due to collemia, stopping the collemia may suffice to cure errors of metabolism, but if the heart is at all weak it will not get stronger while there is much sugar in the blood and this therefore must be cleared out. But if you try to diminish the heteroalbuminemia by diminishing the intake of protein you will have to run the chance of weakening the heart and of thus making matters worse in place of better. For this reason neither albuminuria nor glycosuria will stand protein starvation, for the power of the heart, which is largely dependent on protein supply, determines the greater or lesser effect of collemia. Thus I have had a case of diabetes recently under my care in which the patient did quite well and gained considerable weight on heart tonics with diabetic diet and plentiful protein; but when he went out of hospital and got into poor circumstances so that he could get neither the diabetic diet nor sufficient protein, the sugar quickly increased so that on admission for the second time it was more than double what it had been on the previous occasion, and we found along with these conditions no great increase of collemia, but a very marked increase in the weakness of the heart.

Obesity again presents us with a complete parallel of the other defective combustions, and when we see a mountain of fat obstructing our path with a waddle resembling that of a duck, we are certain to see also bolting eyes and to find a blood pressure round about 200 m.m. of mercury and to find that the heart is getting rather tired of continued hard work and is also somewhat encumbered by fat. As these conditions go on and continue, sugar or albumin is common enough in the urine and we have generally defective combustion of all combustibles as well as of fat. We know that the end will be cerebral hemorrhage or heart failure, according to the original structure of the heart and the cerebral vessels, and as one is weaker or stronger than the other. This again is not disease, but merely another side issue in the natural history of chronic food poisoning.

The first stage in this condition was a store of uric acid accumulated in the prime of life, the next was an increasing collemia from its solution leading to rising blood pressure and gradually increasing heart power; when the heart begins to fail in the struggle we get the stage we now see in front of us, obesity, albuminuria, glycosuria, the defective combustions, and these will affect chiefly one or other set of organs according as stress and strain or other conditions of life aid or hinder them in their functioning. Thus if such a patient is much exposed to cold the skin will be unable to continue its functions when hampered by a defective circulation inside and cold without, it will gradually become dry and atrophied and such patient will probably get albuminuria (see "Uric Acid," p. 606). Or if the skin is protected by warm clothing or a good climate the accumulating errors of circulation will produce congestion of stomach, liver, duodenum, pancreas, and spleen, thus affecting the digestion and absorption of food and then glycosuria may be produced in place of albuminuria. All the other phenomena are equally easy to explain, but one thing is now certain, that all these errors of metabolism are due to capillaries obstructed by uric acid and to relative weakness of the heart in varying combinations and that these are but the phenomena of some stages in the course of chronic food poisoning.

To understand this gives complete power of prevention, and such power of relief as is possible in the nature of things. But we have not relieved disease, but have merely put a stop to food poisoning at a certain stage in its development, by removing the cause.

We have here not merely a complete explanation of the circulation phenomena that accompany these metabolic disturbances, but our knowledge is power, we can produce or remove any of them at pleasure. By controlling the uric acid together with the other factor, heart power, we can produce any change in the circulation that is required, and we thus get a complete grasp of what appear on the surface to be the various ways in which this substance acts as a poison. We see that these various ways are apparent rather than real and that it only acts in two ways after all: (1) local irritation, and (2) obstruction of capillaries.

Only when it has produced structural change, when the machinery is broken, shall we fail in removing its effects. By controlling the uric acid we control every function of the body, including the nutrition of the heart and lungs. And having done this you will find that the life of the entire body is under your control and that you can do with it what you will.

You can make it cold or hot, fat or thin, young or old, short or long lived, liable to microbic invasion or immune, harboring parasites or not harboring them, and when you have worked all this through in a sufficient number of cases to realize your power, you will completely understand that there is here no disease, and that a number of names have been quite unnecessarily wasted on various stages of poisoning by one substance which is practically speaking not contained in the natural food of man, and with which he has come into disastrous contact only through an unwise departure from his natural food.

PSYCHOGENETIC DISORDERS; CASES SEEN IN DETAINED IMMIGRANTS.

By HOWARD A. KNOX, M.D.,

ELLIS ISLAND, N. Y.

ASSISTANT SURGEON, U. S. PUBLIC HEALTH SERVICE.

THE first case of psychogenetic neurosis that I remember having heard of was described by a farmer in Connecticut (although he did not use the term) in speaking of a neighbor who had lost his entire fortune in a bank failure and then developed insanity. The farmer said, "I guess the loss of that money turned Sam's head," and since "Sam" immediately recovered after the bank made good its

losses, I am of the opinion that the loss of the money did "turn Sam's head" and that his malady was one of those classified as psychogenetic.

These psychoses are thus termed because one or more distinct psychic experiences stand out as of special etiological importance in definite relation to their course. These experiences in this condition are either of a strongly pleasant or strongly unpleasant nature, especially affective to the patient possessing them. A characteristic of all psychogenetic disturbances, as in the rustic instance cited above, is that they usually disappear very soon after the psychic irritant which produced them is removed or successfully counteracted. Indeed, simple suggestion from a person of strong and pleasing personality will work wonders in most varieties of this neurosis.

Many American investigators are endeavoring to unearth etiological facts in the pathological laboratory and at the autopsy table, forgetting in many cases that there are psychosic symptom complexes whose origin is found purely and exclusively in the psyche. Some neurologists regard hysteria as the only true form of psychogenetic disturbance, but there are many non-hysterical conditions that are due to psychic experience and which cannot be classed with any variety of hysteria yet described. Whether hysteria be due to the repressed painful experiences as suggested by Freud, to the disassociation of Janet,[1] or, according to Moebius'[2] theory, the change of concepts into physical manifestations, it is always seen in individuals of the hysterical type and possessing the hysterical temperament, and is most often seen in members of an emotional race. Non-hysterical psychogenetic disorders may be seen in normally balanced individuals, in many cases in persons who have led a calm, even, easy life where strife has been unnecessary and hence no mental immunity to untoward experience has been acquired. They are seen in otherwise average persons who have been raised amid contracted surroundings, as in convents or under close parental scrutiny and censure, and in persons who have been the recipients of suggestion that certain acts and practices were wholly bad and subjected the perpetrator to certain condemnation. Individuals with the latter extreme ideas would naturally be affected more adversely when brought into contact with these same acts and practices than persons reared amid more natural conditions. One sees patients whose mental disorder can be definitely traced to one emotional shock, such as the death of a loved one, loss of money, the circulation of a scandalous rumor, sudden fame or the acquisition of wealth. Laymen have, of course, attributed insanity to such causes as these before medical men regarded them seriously.

Most of the dementia præcox cases that "recovered" and most of the maniac-depressive cases that "never recurred" were cases of psychogenetic neurosis, and in substantiation of this statement I wish to cite a case that has recently come to my notice.

Case I.—Female, aged, 26, married; detained at Ellis Island pending communication with her husband who was in the United States. She had never before left her native town and, of course, the change of environment, involuntary confinement, strange surroundings, customs and people, with the uncertainty of the ultimate disposition of her case, were conditions to which she might well act adversely. Her personal and family history (according to herself) were negative, but histories usually are in the case of immigrants, so this was hardly reliable. She had apparently been normal until one afternoon, while making rounds as officer of the day, I observed her in an attitude of supplication, which attitude she had held continuously for over two hours. She was at this time absolutely mute, although later the same afternoon she took up a stereotyped expression which was repeated for about fifteen minutes, when she became practically normal. The following afternoon she was in a condition which I took to be Ganser's twilight syndrome, in which she was highly impressionable to actions and words spoken near her. I suggested in her presence and in her own language that she be allowed to go to her husband in America. Immediately she was out of her stupor and attempting to thank me for my supposed kindness. The following day she was in a pseudo-stuporous state alternating with periods punctuated by diatribes for anyone who might be near. Cerea flexibilitas was present in the stuporous state. Upon being removed to the psychopathic ward of the General Hospital she cleared and became normal before the medical officer in charge had a chance to examine her. This was her last attack.

Some of the earlier observed facts of this case suggest dementia præcox, but the presence of definite psychic causes and recovery on obtaining that which she desired and on the change of environment point strongly toward psychogenetic disorder. There was none of the theatrical or sympathy-craving seen in hysteria.

Kraepelin has said that immigration stations afford excellent clinical facilities for the study of these disorders, and judging from the cases I have seen and from mistakes which are being made by lay-workers from various schools for the feeble-minded who are not aware of the importance of eliminating functional psychoses when dealing with conditions suggesting mental defect, I am inclined to agree with this learned neurologist. The mistake of not recognizing these disorders is, of course, an excusable one, especially in these non-medical workers, since there are all degrees of psychogenetic disturbance from a slight change of temperament to a condition in which there are psychomotor activity, refusal of food, self-mutilation, homicidal tendencies, and extreme filthiness.

Another case whose symptoms resembled somewhat those of the earliest stage seen in the manic phase of maniac-depressive insanity is the following:

Case II.—A Danish woman, aged 25, single; detained at Ellis Island because of certain legal requirements which had not been fulfilled. She had been in the United States three times before, had worked as a maid at several places in this country and had returned to Europe after each sojourn here as a matron on a liner. She was easily discouraged and was not long satisfied with any place where she was employed; there seemed to be a chronic "wanderlust" which, in order for her to retain her mental equilibrium, must be satiated. She was of pleasing appearance and neatly dressed. After being held for about three days and after having been unable to find out just when she would be permitted to leave she assumed an inimical attitude toward the matrons who had her in charge. She was at first taciturn, then became loquacious. Her smile suggested a facetious, fault-finding trend of thought. She refused to eat the food prepared for her unless it could be served to her in private; she did not wish to associate with other detained immigrants of her own class. She became abusive and indulged in profanity and abusive language. She catechised the physician when he approached but retained her dignity and urbanity until she found out that her whims could not be gratified, whereupon she told the physician what she thought of him in no uncertain terms. She was discursive and vacillating and no answer of any length could be educed regardless of the question. She persisted in her abusive tirades after having been told that such conduct was against her best interests. She was perfectly oriented, always neat in appearance, and physical examination was negative except for a slight general increase of superficial reflexes. Her face was always flushed and a lesser degree of this condition was natural to her. She had no hallucinations of vision or hearing and in fact the sum of her mental aberration consisted in a total misunderstanding of the situation and the relations that existed between the authorities and herself and a vague feeling of impending danger with reactions to the same and chafing at restraint. She was over-aggressive. Upon being re-

moved to the General Hospital she at once became normal but inside of two days was as bad as ever. In the hospital she was restless and agitated. Her condition was a hypomanic one and remained so until she left Ellis Island.

In this case the inability to gratify the unconquerable desire to wander acted as the psychic experience which precipitated the psychosis. The fact that she became normal on admission to the hospital pointed strongly to the diagnosis of psychogenetic excitement.

The nature of psychogenesis has not been fully worked out. According to certain authorities, notably Birnbaum and Bonhoeffer, the ability for mental disorder to result from psychogenetic incitation is evidence of degenerative soil or psychopathic predisposition. The above question is of great importance to the physician engaged in immigration work, since he is often called upon to render an opinion as to whether the psychosis exhibited by a given alien is "due to causes which existed prior to landing." If all of these mental disorders are engrafted on "degenerative soil" then all such cases are due to causes existing prior to landing, and such aliens will be deported. If, on the other hand, psychogenetic psychoses may arise from strong emotional shock subsequent to landing in healthy persons free from psychopathic taint, then the aliens having such disorders are not insane from causes existing prior to landing, and hence will not be deportable. Both, or either of the above conditions are present at times, and it only goes to show that each case must be studied on its own merits and a decision must not be made until all available data have been carefully gone over.

Kraepelin[3] does not believe in the degenerative soil theory, but regards psychogenesis merely as a measure of the personality, temperament, and character of an individual. The fact that one man develops a psychosis upon the death of a near relative and that another does not is merely an indication of the inherent characteristics of each man. Racial trait is important here. Of the three the Italian would be more apt to develop a psychosis under the above condition than would a Dane or Finn, simply because the former will be more affected by the experience, but it does not follow that the first man has a more degenerate nervous system than the other two.

The officers of the Public Health Service at this station are frequently called upon to proceed to certain hospitals for the insane and examine aliens with a view to determining whether causes existed prior to landing. Now many of these cases are ill-defined and atypical, and frequently no diagnosis has been made by the hospital authorities, who, in spite of the latter fact, have in recommending the cases for deportation, certified that the causes in the case existed prior to landing, said causes usually being given as "congenital psychopathic predisposition." No account is taken of psychogenetic disturbances that arose subsequent to landing. The above unscientific, routine method of issuing certificates seems pernicious and unfair to the alien. Glueck[4] is of the opinion that psychogenesis depends upon three factors: (a) the nature of the experience and the affective value which the experience possesses; (b) the degree of acuity with which it has been perceived and the intimacy which it gains to the psyche; (c) the definite character of the "psychic whole," of all the mental processes which have been at work in making an individual precisely what he is. He does not believe that psychogenetic disorders are due to existence of degenerative soil or to defective inhibitory apparatus. He asks, "Does the individual exist about whom we can say 'Here is a man whose nervous system is so stable that it can stand all manner of nervous or mental shock?'" If the emotional shock be strong enough and properly selected to suit the character of the individual, no matter how stable his nervous system, he cannot withstand it.

The symptoms of these psychoses are varied and indefinite and the diagnosis can only be made by studying their origin, course, and termination. They may simulate all other psychoses with the exception that the history will reveal a strongly affective psychic shock which can be educed by psychanalysis if in no other way. The strong influence of environment, the effect of granted desires to whims, along with the results produced in a change of scene (amelioration of symptoms or complete cure) with the absence of hysterical features make up a usual picture in the psychogenetic psychoses. The Ganser syndrome before referred to, is an important condition in this connection and is regarded by some men as hysterical and by others as a degenerative state. In a typical case there is a suspension of all cerebration for the time being. There is complete ignorance of matters of common knowledge; the name, age, and the names of familiar persons and things are absolutely out of reach of the patient. Fabrication is present but answers to questions are not altogether irrelevant, for certain familiar pictures or objects may be mistaken for other similar ones and named accordingly. Despite the above mental disability these patients are well-behaved and orderly. Vivid hallucinations of hearing or sight may be present, yet with these there is present a distinct subconscious state. Recovery occurs in a short time, and the person awakes with amnesia for incidents that transpired during the psychosis. A modification of this syndrome is seen in certain rare cases of dual personality.

Psychogenetic disturbances may result from injury to the head totally apart from the physical trauma induced. There may be a total change in personality, morals, and temperament. There may be periods of months when the patient is in a pseudo-dream state and during which time he manifests various vicious tendencies and other evidences of an altered personality. I have recently testified as an expert witness in the case of a young man who was the victim of such a combination of circumstances, and even though he presented physical signs of traumatic epilepsy (intolerance to alcohol, etc.) I found it difficult to explain the case to the satisfaction of the prosecuting attorney, who was a very practical man with limited powers of imagination and but little ability to grasp ideas of which he had not made a previous study. The recognition of psychogenetic disorders is important in the case of criminals who at the time of their hearing or trial present signs of insanity. The psychosis manifested by these men may be a result of the psychic shock incident to the crime, its discovery, the detection of the offender, and the consideration of the debt that must be paid society. Such criminals are, of course, responsible, and should be tried as soon as their mental condition has cleared, and I am not sure that it is always desirable to wait for this.

Raecke[5] speaks of a complex which he calls an "hysterical stupor in prisoners," and which is sometimes seen at immigrant stations, especially in immigrants from Latin countries; it is seen by medical officers in the army in the cases of young recruits

subjected to discipline foreign to their previous experiences. Catatonic manifestations are present in Raecke's stupor and in the cases that persist for months a diagnosis of catatonic dementia præcox may be made with the correspondingly bad prognosis, especially since such cases may present such symptoms as impulsivenes, silliness, verbigeration, stereotypy, grimacing, and the assuming of attitudes, Ganser's complexes may enter into cases of Raecke's stupor, and with the delusions and hallucinations that are sometimes present a diagnosis can be only tentative, yet dementia præcox can be excluded by the fact that in both Raecke's stupor and Ganser's twilight state the patient is sensitive to impressions arising in his immediate external surroundings, and these impressions may at any time cause him to become normal in mentality and action. The importance of and the reason for here mentioning this stupor and syndrome lies in the fact that one should be cautious about rendering a bad prognosis to the relatives of seeming præcox cases and in giving an unconditional diagnosis of catatonic dementia præcox after brief observation.

CONCLUSIONS.

(1) Psychogenesis is important in considering whether or not a given psychosis is founded on degenerative soil and hence whether the cause of a given alien's insanity existed prior to landing. Cases occur in which psychoses have arisen in healthy persons with apparently normal nervous endowment.

(2) Psychogenetic disorders are important to all who are identified with medicolegal problems since, as Glueck[6] says, most of the psychoses of criminals are psychogenetic in character.

(3) A knowledge of psychogenetic disorders is necessary in making accurate diagnoses and especially prognoses in traumatic and other organic mental diseases or supposed diseases of this nature.

(4) Immigrants suffering from psychogenetic disorders should not be examined for defectiveness while in this state, and lay-workers with no knowledge of medicine, psychiatry, or neurology, cannot detect these conditions but would call such a patient "stupid" or rate him as "seven years old on the Binet."

THIRTY HEADS IN MESIAL SECTION.

AIR SINUSES.

By R. H. WOODS,

CHICAGO, ILL.

DEMONSTRATOR IN ANATOMY, DEPARTMENT OF MEDICINE, UNIVERSITY OF ILLINOIS.

Since the Alexandrian age anatomists have been compiling records and noting the various structures in each body opened, as to their attributes and those organs which occurred within certain limits the greatest number of times were taken as "usual" or normal, noting at the same time the various differences and their percentage of frequency. Nature shapes each organism after a certain pattern, but due to heredity, parental discrepancies, birth difficulties, sex, race, climate, housing, nature of diet, hygiene, and a thousand and one other environmental factors which demand for each particular organism a special design of structure to best enable it to sustain life, she varies the pattern by structural changes and differences normal for that particular one. These same variations to another are superfluous and abnormal, depending again on its fundamental needs in beginning and sustaining life. In each the same general pattern is followed, but with such marked variations as to make each individual a type by itself. These facts are particularly emphasized by the great variety of differences found in the nasal cavities.

The practitioner and student will recall the anatomy of the nasal walls briefly, thinking of the cribriform plate above, the hard palate below, the septum dividing the cavity into two lateral halves, the three swell bodies and three meatuses with the bulla ethmoidalis and the uncinate ethmoidalis with the hiatus semilunaris between them on the outer wall. He recalls the anterior and the posterior groups of ethmoidal cells in the body of that bone; the antrum of Highmore in the body of the superior maxillary bone; the frontal sinus above the orbits; sphenoidal sinus in the body of that bone. All are lined with mucous membrane, communicating with the nasal cavity and containing air. He recalls Series No. 1 (Ballenger's terminology), consisting of the frontal sinus and its infundibulum, the anterior ethmoidal cells and antrum of Highmore, as draining into the hiatus semilunaris under the middle turbinate; and Series No. 2, consisting of the sphenoidal sinus draining into the sphenoethmoidal recess above the superior turbinate and the posterior ethmoidal cells below it. But, if this same practitioner or student had the opportunity and would take advantage of it, he would have his ideas and ideals of the nasal cavity and its accessory air cells much changed. While the same general pattern is maintained, the variations are extreme, so much so that it is practically impossible to classify into varieties from a limited number of specimens. One could start early and work late, going from table to table day after day, dissecting and carefully probing and not find two heads alike.

It has been the writer's pleasurable duty to examine a goodly number of specimens in mesial section and in this work notations were made in cases showing differences from the usual, and since every one showed some variation, the notations grew to enormous proportions. With this consideration it becomes necessary to sift the matter down to a few specimens to show the anatomical possibilities. In this review of specimens the major part of interest is lost by the absence of the case history. One can only draw on the imagination as to the possibility of nasal difficulty. In 90 per cent. of the material dissected no evidence of accumulation in the air cells or sinuses was found. In those showing these accumulations, the drainage openings, location and size of the cells and spaces corresponded as closely to the classical description as any of the others. Here the difficulty as to conclusion arises, since the accumulations may have been part of the terminal phenomena plus saprophytic activity. As before stated, we cannot review each dissection, hence a few specimens are picked at random, so the reader can see for himself what may be anticipated in the general run of sinus cases.

A.—The frontal sinus was large, extending far outward in the orbital ridges and continuous with one large anterior ethmoidal sinus (cell) behind. These opened into the bulla ethmoidalis which had its exit posteriorly and superiorly into the hiatus semilunaris. A middle group of ethmoidal cells (one single space) was separated from the anterior and posterior group by a bony wall; this space drained from its inferior aspect into the hiatus. The sphenoidal sinus was a large chamber occupying all of the body of that bone and extending into the basilar process of the occipital bone 15 mm. and laterally 25 mm. from the median line into the lesser wings of the sphenoid above the sphenoidal fissure. This left the body of the sphenoid a mere shell of bone. It drained into the recess as usual and communicated by a large foramen to the posterior ethmoidal group. This latter also consisted of a large single cell which drained into middle meatus. The opening from the maxillary sinus was below the hiatus semilunaris as very frequently found in other specimens. A mastoid had been done on this cadaver, it, too, as with the other air spaces, consisted of only a shell of bone. The general bony structure of the remainder of the head was normal (usual).

B.—There was nothing marked with the frontal sinus. The anterior ethmoid group was composed of many small cells communicating with and projecting or overhanging in such a way as to be continuous with the superior swell body. The posterior group consisted of one large sinus continuous below with many small ones in the enlarged superior turbinal. The posterior group was partitioned off from the anterior, though each had continuations into the superior turbinate, both groups drained into the middle meatus, no other openings were found. The sphenoidal sinus was very large, with shell-like bony wall, and drained into the recess as is usual. Antrum opened below hiatus.

C.—The frontal was of average size, and drained as is usual. The anterior ethmoidal cells were large and few in number, having comparatively thick bony walls and draining from below through many oval openings into a very large middle turbinate which also had firm bony walls. This middle turbinate was a sinus by itself, being hollow, the inner surface of its walls was marked by a few longitudinal ridges directed upward toward its exit which was located superoanteriorly and emptied into the hiatus. This large middle turbinate incorporated the bulla ethmoidalis. The maxillary sinus presented its opening 4 mm. below the hiatus. Series No. 2 drained in usual way, but the openings were large and cells large.

D.—Exceptionally large bulla ethmoidals. The antrum presented three openings, one into the hiatus and two below it. Two other specimens presented multiple openings from the antrum of Highmore. These hardly could have been operative in origin, since they were too high and too far back.

E.—The frontal sinus was as usual. The anterior ethmoidal cells were comparatively large and continuous below with a chain of six cells in the lateral wall of the cavity anterior to the turbinates and extending downward to the level of the inferior turbinate. The bulla ethmoidalis was a part of this chain. Below the bulla the nasal wall was smooth. Between the chain of cells and the antrum only a very thin wall of bone existed. This chain of cells drained upward through the bulla into the infundibulum. The antrum opened 3 mm. below hiatus. Posterior ethmoidal and sphenoidal cells composed of one large sinus with two points of drainage as would be normal for these spaces.

F.—The frontal sinus contracted. The infundibulum scarcely patent. The nasal cavity was generally contracted and narrow. The anterior ethmoidal and posterior ethmoidal cells were only a thin row of contracted cells; the distance between nasal cavity and orbit was about 5 mm. The opening from each set was tiny, those from the antrum and sphenoid would admit only a pin. The sphenoidal sinus scarcely existed, the body of the bone being filled by spongy bone, except pea sized spaces having trabeculæ on either side.

G.—The frontal sinus was of considerable size, consisting of one space with a large opening into the bulla. The bulla was large and communicated to the middle turbinate which was sinus like in its whole extent, but did not appear to be of exaggerated size from superficial inspection. The cavity of the middle turbinate drained anteriorly into a tube like structure which represented the end of the infundibulum. The remainder of the cells and sinuses were of the small cell type and drained as usual. Both sides alike.

H.—The frontal sinus was large, and the infundibulum directed nearly horizontally backward below a tiny ridge posteriorly. This ridge represented the middle turbinate, its length being about that of the superior turbinate, which was in every way usual. The diminutive middle turbinate was hollow and was continuous in front with an enlargement representing the bulla ethmoidalis incorporated with the anterior ethmoidal group. There were no traces of an inferior swell body on this side, but where it should be was an opening 15 mm. across, leading to the antrum. The opening of the nasal duct was present in its usual location. On the other side (left) the two upper turbinates and frontal sinuses corresponded to those on the right. The opening to the antrum was some smaller. Representing the inferior turbinate was a ridge 3 mm. high very close to the floor of the nose. The tear duct opened above it. The sphenoidal sinuses were large on both sides, separated by a septum. They ran far forward and were continuous with the posterior ethmoidal group. We believed these findings to be congenital rather than post operative or atrophic, because of the symmetry, the generally enlarged cavities and the irregularities of the middle turbinates, also an intact septum.

I.—In this group of thirty specimens only two badly bent septa were noted. One in particular stood out with interest. The septum executed a wide sweeping curve from above downward with the concavity to the left. It measured 5 mm. from the perpendicular at its summit. The left inferior turbinate was immensely hypertrophied, the other two of that side being of average size. There seemed to be ample room between the septum and the turbinates, because of the curvature of the former. A surprise awaited us on the right side. A thin probe was passed in at the anterior nares to emerge through posterior nares. This could be swept over the septum between the turbinates without meeting resistance. On removing the septum a nearly straight ridge at the level of the inferior meatus ran anteroposteriorly and crossed the vomer and triangular cartilage. The turbinates on this side were found to recede, together with the entire wall into the antrum, decreasing the content of that space very markedly, but as we saw this compensated for the bent septum by leaving a free space between the swell bodies and the septum. A further compensation was noted in that each air space on both sides was drained and ventilated by a large foramen.

J.—The frontal sinus was of usual size and with the usual drainage. The ethmoidal cells were of small type. Both sets drained from their floor. The antrum opened as usual. The sphenoidal sinuses were of the single cell type divided by a septum, the walls of which were 1 mm. thick. No opening to the sphenoethmoidal recess or to the posterior ethmoidal cells could be found, but a pin size orifice was found at the lower anterior angle into the nasopharynx. The condition was symmetrical.

K.—One of the group presented interesting fetal remains in the nature of two deep but narrow tube like structures ending blindly, whose openings were 2 mm. in diameter and situated in the nasopharynx in relation to the Eustachian tube. One of these cecal tube openings was situated vertically from the Eustachian orifice 13 mm. The other was 10 mm. from the Eustachian orifice anteriosuperiorly and about the same distance in front and below the first named malformation. These appeared to be lined by mucous membrane. They ended blindly in the tissues of the neck, but no external markings were evident as dimpling or weakened fascia. The conclusion, since the condition was symmetrical, was that the pouches were remains of the branchial clefts. One other specimen presented a similar condition, but only one fistula on each side.

L.—Another of the group presented an enlargement on the soft palate directed into the nasopharynx. It was 15 mm. in diameter and rose to an elevation of 7 mm. above its base, circumscribed, firmly adherent, and of a lymphoid like appearance. The question arose as to its being a new growth or a malformation. We cannot stain cadaveric tissue, because of the deterioration, and since lymphoid tissue in the pharynx in these specimens is always atrophic and not demonstrable we believed this to be a new growth and not an extra tonsil.

Summary.—The frontal sinus and both groups of ethmoidal cells drain from their inferior aspect, no exceptions to this being found. Two frontal sinuses were found to drain into the bulla ethmoidalis and this structure to open from its superior aspect. One frontal sinus drained into a sinus like middle turbinate, another one horizontally backwards into a hollow superior turbinate. One specimen had

three symmetrical sets of ethmoidal cells, another had a continuation of the anterior set down in the lateral wall of the nasal cavity to the anterior end of the inferior turbinate. Ethmoidal cells were found to be any shape, size or arrangement, one can possibly imagine, both symmetrical and asymmetrical, ranging from sinus to pin head sized cells. In approximately 60 per cent. of the cases the antrum of Highmore opened where it is supposed to. In the remainder it was found at various points, but always above the level of its floor. One specimen presented the opening above the middle turbinate 5 mm. in diameter, two others had multiple openings on both sides. In four the foramen was so situated in the floor of the hiatus and covered by a marked overhang of the uncinate ethmoidalis that any exudate from the remainder of Series No. 1 would precipitate inevitably into the antrum. The sphenoidal, as with the antrum, invariably drained poorly from a small foramen situated far above its floor. One unusual exception in which it drained from its inferior aspect into the nasopharynx. In ten per cent of this series the body of the sphenoid was composed of spongy bone with small air spaces on each side. In another 10 per cent. the body was a mere eggshell affair occupied by one large sinus. The remainder were septate with medium thick (2 to 4 mm.) bony walls surrounding the air spaces. Three pairs of turbinates which appeared hypertrophied proved to be hollow and sinus like. Only two badly deviated septa were encountered in this series; one of these showed marked compensatory changes. These few observations only illustrate what the rhinologist already knows regarding the complex situation he is to encounter in his specialty. They also illustrate to those of us who contemplate entering this field in the surgical world the necessity of being well prepared with knowledge amplified by experience before allowing nerve to overshadow judgment.

1803 West Adams Street.

THE PHYSIOLOGICAL TREATMENT OF FLAT FOOT.*

By JACOB TESCHNER, M.D.,

NEW YORK.

I shall attempt to give you as terse and lucid an exposition of this subject as the short time allotted to this paper will allow, and shall not enter into the preparatory treatment of the graver and more advanced forms of flat foot, but shall confine myself to that class of cases which give discomfort and pain, with or without deformity and which comprise by far the great majority of cases.

The tremendous importance of this subject can hardly be estimated. Often, when man, woman or child complains of pain or a tired feeling in the feet or legs the lay or professional diagnosis of flat foot on "sunken arch" is made, and treatment by various devices in shoes and arch supports are instituted which invariably tend to aggravate existing conditions and actually produce a flat foot if it has not already existed. There is no denying the fact that patients do get relief for a time from almost any device which alters the position of the weight bearing foot, but therein lies the danger of the production of actual structural changes. The treatment is pernicious whether given by the specialist, the general practitioner, the shoemaker, or the shoe vender. The specialist carefully makes a cast of the foot and has a brace or arch support, and a shoe constructed upon it. No cast is ever made with the foot in proper position and bearing the weight of the body, and as the foot assumes an entirely different shape in action, a cast of a passive foot can be of no value. The general practitioner simply sends the patient to a shoemaker who works for specialists or to a shoe vender who advertises more or less extensively. They either use braces or build up the shoes with stiff counters or both and actually render any improvement impossible. Every brace and every stiffening of the shoe *prevents proper ankle motion and forces the foot into a position of eversion, and thus prohibits the use of the ankle joint in walking.*

No shoe that can be constructed is curative. The shoe that should be ordered is one that will permit absolute freedom of ankle and toe action and should fit closely in the arch and heel. The width of sole must be sufficient to permit the entire weight bearing foot to rest upon the sole. The broad part of the inner side of the sole must be extended sufficiently backward to permit the entire ball of the foot to rest upon it and the arch of the shoe must be short. Any support which may give temporary relief is vicious because it causes the weight to be borne upon the inner arch, which is unphysiological.

The anatomical and physiological studies of the foot have positively demonstrated that the inner arch was never intended to bear weight, hence the use of an arch support is unphysiological and fallacious.

The condition of flat foot is due to a faulty gait, occasioned by many varied causes, all of which tend to faulty muscular action. Hand-led children of the wealthier classes are more prone to this condition than the neglected and often shoeless children of the tenement. When the school age arrives they receive the pernicious instruction to toe out in "attention." The same thing is invariably taught in dancing schools. Later in life occupation plays an important part in the causation of flat foot. Those who are upon their feet the greater part of the day and whose activities are limited to a few steps at a time and then standing, as nurses, men on the floors of exchanges, barbers, waiters, shopkeepers, etc., are specially prone to acquire this condition, the main cause being that when they stand they do so with the feet everted, and the thighs and legs are used as pegs, permitting the arches to sink. After sprains of the ankle the timidity due to the pain caused by the proper use of the ankle joint causes eversion and consequent flat foot. The affected swagger of young swains to acquire a distinguished aristocratic gait in their promenades rarely fails to produce flat or weak feet. This is especially noticeable among Austrian army officers who appear to consider it a distinction to have flat feet, round shoulders and hollow chests. The lack of tonicity and the lack of proper and concerted action of the muscles of the hip, thigh, leg and foot are the real causative factors, not excluding the pose of the trunk. The education and strengthening of the muscles will bring about a proper gait, and a cure will be effected. The patient with a flat foot or flat feet has a swaying gait because the weight of the body is alternately swung from one

*Read at a meeting of the Medical Society of the County of New York, April 21, 1913.

leg used as a peg to the other, used in the same manner.

The power of balance upon one foot is partially or totally destroyed by improper use. This can be readily taught and restored. When the full weight of the body is carried upon the balancing foot the arch is considerably and visibly raised by muscular action. The elements of the proper gait are taught in conjunction with the acquired balance to eliminate the swaying of the body and to give a propulsive impulse to the step. The outward rotation of the thigh, and the pointing of the knee outward and upward must be overcome in order to insure the placing of the toes forward at each step. These exercises and their effect can be readily demonstrated, but it is hardly possible to give an intelligible description because the closest attention must be given to the most minute details of the various movements. The exercises must be demonstrated to be understood.

The results of this treatment are inevitable, positive, and very rapid, so much so that the majority of the distressed ones are relieved within one week, the arch is perceptibly raised within a month, and the formerly prominent maleolus is no longer in evidence.

This has been my universal experience for almost twenty years, during which time I have never used a support of any kind. The faults in each case must be carefully studied in order to rapidly and thoroughly correct the existing faulty gait and deformity or both, and the disability caused thereby.

The exercises are few in number, and can readily be executed by the patient in ten minutes, and should be persisted in night and morning. They should be done in bare or stockinged feet so that every part of the foot, including the toes, should have free play. Nothing can be more patent than the very rapid improvement and relief which is obtained by this method of treatment, and all that is desired is usually accomplished in from three to five visits.

An intelligent and unbiased consideration of the subject of this paper cannot fail to shatter the traditions of the hitherto accepted and almost universal unphysiological treatment of flat foot.

1187 Lexington Avenue.

NOTE ON THE INFLUENCE OF FOMITES IN THE TRANSMISSION OF DISEASE.

By J. T. AINSLIE WALKER,

NEW YORK,

FELLOW OF THE ROYAL SOCIETY OF MEDICINE, FELLOW OF THE CHEMICAL SOCIETY.

The report of the Committee on Communicable Diseases, published in the *American Journal of Public Health* for April, contains a number of expressions of opinion in regard to measles and scarlet fever, which, in the interests of public health, should not be allowed to pass without comment. Both measles and scarlet fever, the committee state, are transmitted by means of the nasopharyngeal secretions and not by the scales of desquamation; in regard to measles, they add, "a child may infect others before the appearance of the rash or during the catarrhal stage." It is therefore surprising to read that it seems to make little difference whether the premises are disinfected or not, and that "it is fairly well admitted by all observers that measles is not transmitted by means of fomites."

Admitting as they do, the infectivity of the nasopharyngeal secretions, it surely follows that any dust on the floor of the sickroom with which these discharges may come in contact is liable to become infected; from this, again, it follows that not merely terminal disinfection, but daily systematic disinfection throughout the course of the disease is clearly indicated as a precaution which should never be omitted.

The view expressed in the report that scarlet fever "is transmitted by contact alone and that all apparent evidence to the contrary is based on lack of knowledge or a misapprehension of facts," will be accepted by few public health workers. The committee are certainly not justified in asserting that "the evidence in favor of transmission by fomites is growing less." Transmission by fomites may be doubted in certain quarters but there still exists a considerable volume of opinion in favor of the more rational view that while direct infection is probably the commoner method, indirect infection cannot safely be ignored: or as expressed in an editorial in the *Medical Council* for May, "the only perfectly safe fomites are the thoroughly disinfected ones."

In this connection it may be interesting to recall an incident related by Sir Ernest Shackleton on his return from his unsuccessful attempt to reach the pole. Some articles of clothing were taken from a chest which had not been opened from the start of the expedition three months before, and which consequently had no opportunity of becoming infected during the latter period. This clothing was distributed among six members of the party, four of whom within 36 hours developed septic sore throats. Having regard to the fact that the party had been living in the frozen regions for the greater part of the period mentioned—*i.e.* away from all other possible sources of infection—and were at the time in robust health, this incident in itself proves conclusively that infection can readily be transmitted by means of fomites. This term is defined in the committee's report of 1911 as "articles which retain the infection for a considerable period of time"; no reference is made to dust—the most active of all fomites—notwithstanding the fact that Prof. C. A. E. Winslow recently obtained 22,700 acid-forming streptococci per gram from an average of 19 samples of dust taken from New York schoolrooms, as described in the *American Journal of Public Health*, September, 1912.

The committee quote Dr. Morton, superintendent of a Scottish hospital in support of their contention that indirect infection may be ignored and that consequently disinfection is unnecessary. Against this British authority may be cited the following: English Local Government Board: "Proper ventilation of schoolrooms, avoidance of overcrowding, cleanliness, and, where needed, disinfection of schoolrooms and school appliances, do much to prevent the spread of infectious diseases." Scotch Local Government Board: "The local authority should also endeavor to see that disinfection is carried out in all places of public resort. They should arrange with the persons in charge of schools, churches, halls, theatres, markets, railway stations, etc., to have those places periodically disinfected by the officers of the local authority. The disinfection of public conveyances, such as railway carriages, tramcars, omnibuses, hackney carriages, etc., should also receive attention." Scotch Education Department:

"Periodic disinfection is advisable, even when no known infectious disease has been present." Urban District Councils Association: "That in the interests of public health it is desirable in the opinion of this Conference of Urban District Councils of England and Wales, that a regular system of disinfection be established in every school." Dr. Henry Kenwood, Chadwick Professor of Hygiene in the University of London: "These 'missed' early or mild cases spread much infection in school classrooms, and despite all the medical officers of health, the medical inspectors of schools, and the most skilled co-operation of school teachers may be able to achieve, this unrecognized infection will continue, in a reduced measure, to be a menace to the health of school children; and frequent disinfection is an easily practicable means of reducing its potency for evil." Dr. James Niven, Medical Officer of Health, Manchester: "If a number of cases of scarlet fever have appeared in any class or classes, the rooms occupied by these should be disinfected. This may also be usefully carried out in the case of diphtheria." Dr. A. Bostock Hill, Medical Officer of Health, Warwickshire: "I would again commend the absolute necessity of disinfection of dwellings and bedding being taken as a routine procedure." Dr. H. Scurfield, Medical Officer of Health, Sheffield: "For dealing with recognizable human infections, the great thing is to have a comprehensive scheme, and for this purpose, we want * * * home visiting of notified cases by visitors on the lookout for other cases among the 'contacts,' visiting of workplaces where necessary, and as a result of these visits, disinfection and removal of defects." Dr. H. W. Baillie, Medical Officer of Health, Belfast: "This [disinfection] is one of the most important precautions for the prevention of infectious diseases, and unless it is thoroughly carried out all other measures must fail."

On this question of the transmission of infection by fomites, the committee appear to have fallen into the common error of assuming that because the aerial convection theory has been abandoned, all infection must necessarily be of a direct nature: *in medio tutissimus ibis* is a safe maxim to apply in discussions of this nature. The committee express the opinion that "terminal room disinfection as at present practised by the average Board of Health, has little effect in controlling the spread of infection and that it appears, in so far as figures are available, that the percentage of return cases is practically the same in those communities where disinfection is compulsory as in those where it is not required." This view is probably correct, though not for the reason which influenced the committee in arriving at it. Room disinfection "as practised by the average Board of Health" generally consists of fumigation with formaldehyde, a method which recent investigations have shown to be absolutely unreliable.

The *British Medical Journal*, as far back as 1894, when referring to the disinfection of rooms by fumigation, said: "On the ground even of economy there is no comparison between this obsolete process and a disinfectant spray; and while cases of renewed house infection are familiar to almost every medical officer in this country, we have Dr. Dujardin-Beaumetz's authority for saying that where the disinfectant spray has been introduced they are practically unknown in France."

THE PRESENT STATUS OF ESOPHAGOSCOPY IN CANCER OF THE ESOPHAGUS.*

By RICHARD LEWISOHN, M.D.,

New York.

The visual inspection of the esophagus (esophagoscopy) as a diagnostic method for cancer and other lesions of the esophagus is by no means of recent date. Mikulicz's[1] extensive experimental work, which showed conclusively the feasibility of introducing straight tubes into the esophagus down to the cardia, dates back about thirty years. In spite of the fact that this method is not new, there is even today considerable discussion as to its value. The examination of the bladder with the cystoscope, which scarcely antedates esophagoscopy, is today well established as a diagnostic method. The position, however, of esophagoscopy is still a doubtful one. Some claim that the method is entirely satisfactory and that it is so simple that it can be applied to any esophageal case; others declare that esophagoscopy is too dangerous for general use and that the value of the diagnostic data obtained by the method is in no proportion to the serious discomforts and dangers to which the patient is subjected. It is my intention to give you this evening an impartial review of the entire question, and I hope to show you that the true solution of the situation can as usual be found between these two extremes. To be sure, the method may have its limitations, but its significance as a diagnostic aid has been in general too much underestimated.

Mikulicz was the first to show in a larger number of cases that it is possible by means of more or less marked hyperextension of the head, converting the right angle normally existing between the oral cavity and the esophagus into an approximate straight line, to introduce a straight tube into the esophagus as far as the cardia. This method, for the sake of brevity, we might call straight esophagoscopy. There is no question that in the hands of experienced examiners this method has been a most successful one in a large number of cases. It must be admitted, however, that straight esophagoscopy can not be called a popular method. The introduction of these straight tubes is in many cases associated with great discomfort to the patient. The hyperextension of the head is often an extremely uncomfortable position for the patient, especially if the spine is more or less rigid. When the teeth are all well preserved, the introduction is frequently very difficult. It is well known that the use of these tubes has been followed by a large proportion of perforations of the esophagus with fatal results. One of the reasons for this is that the tube can not be inserted in the longitudinal position of the esophagus even when the head is in extreme extension. There always exists a more or less obtuse angle between the tube and the esophagus and thus it is easily possible, especially when a certain amount of force is used, to crush the esophagus against the vertebral column and perforate the organ.

Because the introduction of these instruments, in spite of the fact that much has been accomplished with them, is not quite satisfactory, many attempts have been made in the last twenty to thirty years to substitute a new principle of construction for these straight tubes. The large number of attempts

*Read at a symposium on cancer of the esophagus at the Harlem Medical Society, March 5, 1913.

in this direction proves that the last word in this question has not yet been spoken. I mention here another plan that has been frequently used to simplify the introduction of the instrument, namely, the principle of jointed tubes. These tubes are constructed on a number of hinged joints, which after their introduction either snap into place automatically or by means of a wire are pulled straight. Notwithstanding the fact that it is not necessary to hyperextend the head, the introduction of this type of instrument is not very much easier than that of the straight tube.

So much for the straight and jointed tubes. A third principle of construction, which I have introduced into this field of work, is the rectangular telescopic one.[1] I shall not take up your time with the description of this new model. The scope of my subject is a much larger one than the mere detailed description of an instrument. I can not refrain, however, from calling attention to its advantages compared with other instruments. Its introduction is possible in the normal position of the head: it is so constructed that it actually passes in the longitudinal axis of the esophagus, and the introduction in the majority of cases is decidedly easier, less annoying, and less dangerous to the patient than that of the straight tube. Compared with the straight tube the disadvantages of the new instrument are that it brings into view only lesions below the cricoid cartilage, and that instrumentation through it is somewhat more difficult than through the straight tube.

To avoid accidents we must be very careful in the selection of our cases. Any instrumentation is contraindicated in cases where symptoms of threatened perforation into the lungs or mediastinum exist. Patients have been frequently brought to me suffering from severe cough and purulent expectoration in addition to their dysphagia. It is better to avoid passing an instrument in such cases. The danger of inspecting the esophagus in such advanced and obvious cases is out of all proportion to the advantage that might be gained by the inspection.

The cases with extensive mucous secretion, which are by no means rare, offer considerable difficulties in the examination. This secretion is frequently so abundant that it is impossible to obtain a clear picture. So much mucus accumulates at the bottom of the tube in the short space of time between the swathing or aspiration of the mucus and the withdrawal of the swab or aspirator that the visual field is obscured. Even the repeated use of atropine helps little in these cases.

It may be the opinion of some that esophagoscopy is a superfluous measure in the diagnosis of the diseases of the esophagus. I have no doubt that many believe that carcinoma of the esophagus can be readily diagnosed from the history of the case without visual inspection. I am willing to concede this when the patient suffers from marked dysphagia, but then the diagnosis is of little benefit to the patient for by that time the lesion is so far advanced that radical surgical intervention is out of the question. Cancer of the esophagus is a most insidious disease and the neoplasm may exist for some time before definite symptoms of stenosis appear. Early symptoms, such as burning pains in the chest, feeling of oppression, anorexia, etc., may exist for several months prior to the difficulty in swallowing. The only hope we have of radically curing esophageal cancer is when the disease is attacked surgically in its very incipiency. If we had no other reason for the use of an esophagoscope this would be sufficient, for we can make an early diagnosis of cancer of the esophagus only by direct inspection with perhaps the additional help of a subsequent probatory excision. Radiography, though of great value, frequently fails in these early cases.

From the standpoint of differential diagnosis esophagoscopy is frequently of greatest value. It is most important for instance in differentiating intrinsic growth of the esophagus from tumors of the mediastinum compressing that organ. I also believe that esophageal disease is sufficiently common to warrant an extension and popularization of esophagoscopy. The more expert we become in the technique of this method and the more extensively we apply it, the more frequently will we find and diagnose lesions of the esophagus.

I have avoided tiring you with either technical description of different models, their mode of introduction, or the pictures obtained by the inspection of the esophagus. All I wished to do this evening was to impress upon you the importance of esophagoscopy as a diagnostic aid. The direct inspection of the lesions of the esophagus is the most certain method for exact diagnosis. I believe that the possibility of early diagnosis in cancer of the esophagus is possible only if we continue working along these lines, and it is only by means of early diagnosis that we can hope for any successful operative results. Until a few years ago cancer of the thoracic esophagus was regarded as a hopeless malady. Only since Saubruch's inspired discovery has the picture changed. On all sides, in every land, attempts are being made to find a method for the radical cure of these unfortunates. To be sure the results up to date have not been very encouraging. It is to be hoped that further work in this field will eventually make it possible for the surgeon to resect a cancer of the lower esophagus as successfully as he can today excise a carcinoma of the cervical portion.

NEGATIVE ROENTGENOLOGICAL DIAGNOSIS IN CLINICALLY DIAGNOSED GASTRIC CARCINOMA.

By G. H. STOVER, M.D.,

DENVER, COLO.

So definite are the röntgenological evidences in gastroenterology, that at the present time no surgeon is justified in operating upon the stomach, except in emergency, unless he has availed himself of the information given by röntgenological examination, provided, of course, that the services of one skilled in this method are obtainable. Neither is the internist justified in giving medical treatment in chronic digestive disease unless he has completed his examination and either fortified or corrected his diagnosis by means of röntgenology.

To many this may seem to be an overstrong statement; by those, however, who are reasonably familiar with the diagnostic results of these examinations, the statement must be recognized as one that before long will be generally accepted.

There have been brought forth many remarkably ingenious aids to gastroenterological diagnosis; the diagnostic acumen of many practitioners of the specialty compels admiration; the röntgenological examination is but one of many means to be used

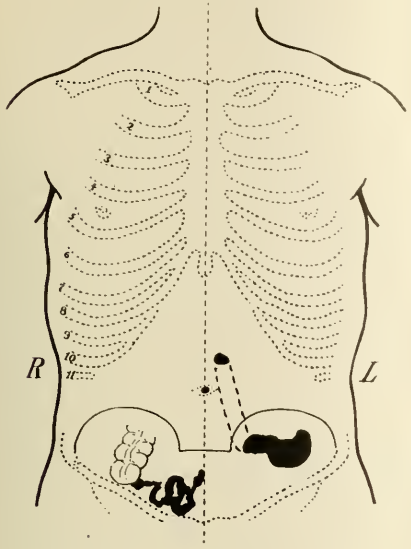

Fig. 1.—Six-hour residue; obstruction at the cecum.

in the search of these cases, but it is one of the most important of all. Like most of the special diagnostic methods, special equipment is required and

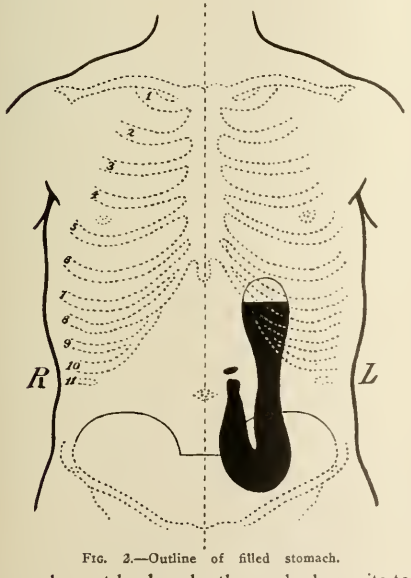

Fig. 2.—Outline of filled stomach.

the work must be done by those who know its technique. It is a method devoid of unpleasantness or danger to the patient. The case here cited is a striking illustration of my attitude on this subject:

Sister Mary S.—Aged 49. Stomach trouble for a long time. She presents emaciation, anorexia, constant pain, cachectic color of skin; very frequent vomiting; blood has been vomited; absence of HCl in stomach contents; an apparent tumor palpable. She was about to be operated upon, on account of the very plain clinical diagnosis of carcinoma of the stomach; the operation was looked upon as being a last-resort measure and the prognosis was gloomy. She was sent to me, not for diagnosis, but simply as an interesting case for study.

Röntgen examination April 30, 1912, Holtzknecht and Haudek method, five plates being made. There was a considerable six-hour residue, very low-sitting, to left of median line, full rounded outline, with a neck directed toward the right. (Fig. 1.) Further serial plates gave the following: Fig. 2. High-sitting pylorus; body of stomach greatly ptosed, the greater curvature being far below the crest of the ileum; peristaltic waves very shallow and infrequent; first meal arrested at ileocecal junction. The following written diagnosis was made: "No carcinoma; adhesions probably to (spleen and) gall bladder causing pyloric stenosis; there may possibly be a secondary (pressure) ulcer. Obstruction at ileocecal junction."

Operation: gastroenterostomy (Finney), appendectomy, and enteroenterostomy, was made by Dr. Leonard Freeman shortly thereafter, the findings completely confirming the röntgenological diagnosis. There was no sign of carcinoma; there were old, dense adhesions to an elongated gall-bladder, causing pyloric obstruction; there was a failure of rotation of the gut, the ileum and cecum having a common mesentenry, thus accounting for the stenosis at the ileocecal junction.

It is now almost a year since the operation, and the patient remains well.

216 Metropolitan Building.

The Clinical History and Morbid Anatomy of a Case of Generalized Scleroderma with Severe Muscular Atrophy.—J. Collier and S. A. Kinnier Wilson report a case of this condition. They state that generalized scleroderma with affection of the muscles is a rare disease and there have not been many pathological investigations of this interesting condition. The case they report is peculiar in that it differs from the group described as "dermatomyositis" in the absence of an acute onset, the absence of acute pain, muscular tenderness, and swelling of the muscles, and the absence of subsequent hardening and contracture in the affected muscles. It is further peculiar in that the distribution of the muscular affection was much more extensive than was the skin affection. In most of the reported cases of scleroderma with myosclerosis the muscular affection has been coextensive with the skin affection and this has given rise to the opinion that the myosclerosis resulted by an extension of the sclerotic process from the skin to the underlying muscles. Brocq, however, has shown that the muscle affection is apart from the skin affection and that the former may be much more extensive than the latter. He considers that an "infiltration" of the muscle comparable with the edema of the skin occurs at first and that this is followed by sclerosis, and his views are echoed by Dinkler, Rosbach, and Unna. The authors have been able to find one case only in the literature of the subject which is comparable to the case that they report and this was recorded by J. A. Nixon, but in Nixon's case the skin was adherent to the underlying tissues, and contractures were present though the muscles were intensely wasted. This case was not investigated pathologically.—*Proceedings of the Royal Society of Medicine.*

THE RELATIONSHIP OF THE THYROID GLAND TO ALIMENTARY TOXEMIA.

During the discussion on alimentary toxemia which, after going on for several weeks at special meetings of the Royal Society of Medicine, London, ended on May 7, several illuminative papers were read. It must be freely acknowledged, however, that much ignorance prevails among the medical profession as to the cause or causes of that condition, which is known, for lack of a more suitable name, as alimentary toxemia or intestinal autointoxication. At this meeting a brief but suggestive paper was read by Frederick Langmead on the relationship of the thyroid gland to alimentary toxemia. Langmead confesses that such relationship is as intangible as any, but says that at the same time it is as likely as any. Arguing that tetany is, in part, brought about by alimentary toxemia, the author thinks it a reasonable inference that the thyroid gland, among its antitoxic functions, includes that of combating poisons absorbed from the intestinal tract. In support of this view the experiences of Arbuthnot Lane, George Rowell, and H. W. Carson are quoted, all having stated that they have seen ileosigmoidostomy followed by shrinking of a goiter.

Again, rheumatoid arthritis is referred to as probably in many cases due to alimentary intoxication. In this condition overgrowth of the thyroid is apt to occur, and also tetany, a symptom of ineffective functioning of the thyroid gland, is found. Moreover, rheumatoid arthritis is occasionally distinctly benefited by the administration of thyroid extract. Perhaps the most conclusive inferences, however, are to be drawn from the researches of Major R. McCarrison, I. M. S., who has studied goiter as it occurs endemically in the valleys of Chitral and Gilgit in northern India. A summary of these researches was embodied in the Milroy Lectures, referred to editorially in the Medical Record, March 8, 1913. Among other things McCarrison demonstrated that thyroid enlargement can be produced experimentally in man within a few weeks by the administration of suspended matter separated by filtration from goiter-producing waters, and can be cured by taking thymol, one of the most powerful of gastrointestinal antiseptics. He showed that if the source of the toxin he avoided the gland will return to normal size, unless secondary changes have occurred. When no such changes have occurred McCarrison has caused goiters to dwindle or disappear by using vaccines prepared from different forms of organisms, a staphylococcus, a coliform bacillus, and a spore-bearing bacillus. Langmead has tried a similar mode of treatment with considerable success.

In summing up Langmead says that the thyroid is a gland, a useful function of which is to counteract intoxication. One of the sources of the intoxication is probably the bowel. If the intoxication be proportionately great for the gland, it undergoes hyperplasia and visible enlargement. If the amount of intoxication can be lessened the extra burden is removed and the gland diminishes. This has been done by the use of thymol and vaccines, especially those prepared from cultures of the coliform organisms obtained from the patient's own intestinal flora. The vaccines generally employed by Langmead were autogenous vaccines of colon bacilli.

It would seem that Langmead has gone some way in the direction of proving that goiter is partly due to intestinal toxemia. At any rate, the facts mentioned in his paper are so remarkably suggestive that they indicate the desirability of further research on the lines pointed out.

THE PSYCHOLOGY OF THE SUFFRAGETTE.

Many persons reading that the British suffragettes have burned, thrown bombs, broken windows, destroyed mail, and committed a hundred and one other seemingly wild acts, have concluded that they are insane or hysterical or, at any rate, not altogether responsible for their actions. However, if the matter be studied more closely it will be observed that judging from results there has been much method in their madness. The suffragette up to a certain point, went far towards gaining her ends, although she has now probably gone too far and has thereby created a strong prejudice against her cause.

In the *Lancet*, May 17, 1913, Claye Shaw endeavors to explain the psychology of the militant suffragist. He draws attention to the fact that few people know the importance of feeling in volitional acts, although it is really one of the essential elements of the mind. Both feeling and emotion are especially well-developed elements of the female mind. So is mono-ideism, or the concentration of consciousness on some subject carrying with it a strong emotional tone. Such in its extreme development, is ecstasy, which, although rare is not an insane condition. In an elaborate argument Wundt shows that personal character is the ultimate cause of volition, and that the connection between motive and volition is uncertain because of the existence of this personal factor, the manner of whose cooperation with external factors is unknown.

Shaw is, therefore, of the opinion that there are no symptoms of insanity or hysteria in the actions of the militant suffragists, but seems disposed to

think that egoism has had much to do with their dangerous and absurd antics. The extreme suffragette is probably as much governed by the love of notoriety as by any other influence. The leaders, or some of the leaders, appear as fond of notoriety as certain eminent politicians, and possibly the psychology of the prominent militant suffragists is near akin to that of several leading lights of the political world. Notoriety is the breath of their nostrils and not to be in the limelight is hard—almost impossible—to bear. Self-advertisement in these days is a habit that, once contracted, is as hard to break as opium taking. This motive impels the acts of perhaps most of the leaders of the suffragettes and of many of the rank and file, although with some personal character is the guiding force. Women, too, are more imitative than men and some of the actions of the militant suffragists are in imitation or in emulation of previous actions by sister militants. In any event, Shaw is undoubtedly right in stating that the explanation of the psychology of the militant suffragist is not to be found in insanity or hysteria.

The Destructiveness of Man.

Every day one sees in a lay journal and once a week in a medical journal, boasting as to the beneficial and wonderful results of advanced civilization. References are made, sometimes rightly and not infrequently wrongly, to the startling results which have come about from some scientific discovery, the reputed cure of some disease, or the wonderful effects of a new surgical procedure. In order, therefore, to keep us becomingly modest, it is as well to point out now and then that all the marvels of modern civilization are not altogether unmixed blessings and that in bygone times the inhabitants of the earth seemed to exist comfortably and healthily enough. Sir Ray Lankester in a second volume of "Science from an Easy Chair" brings home to us the fact that man in attempting to order the ways of the world so as best to suit his own convenience and pleasure, has not been entirely successful in accomplishing this object. He shows that man ever since his appearance on the earth has been an instrument of destruction. He has burned up forests, produced deserts, and polluted rivers. Indeed, according to Lankester, the most repulsive of the destructive results of human expansion is the poisoning of rivers and the consequent extinction in them of fish and of well-nigh every living thing save mould and bacteria. The sight of one of these death-stricken black filth gutters makes one shudder as the picture rises in one's mind of a world in which all the rivers and the waters of the seashore will be thus dedicated to acrid sterility and the meadows and hillsides will be drenched with nauseating chemical manures. Such a state of things is possibly in store for future generations of men. These words of the British scientist should awake an echo on this side of the Atlantic, for in no country of the world have the beauties of nature been so wantonly defaced as here and in no land have the rivers and lakes been so polluted to satisfy the greed of the individual. Of course, it is a mistaken policy, for such flagrant disregard for the health of the masses will result in disaster. However, this point of view is receiving tardy recognition, and in future typhoid fever, for instance, will not be spread far and wide by neglect to prevent the pollution of waters. There is a long road yet to travel ere the prevention of disease and the public health are regarded in their proper light. *Salus populi, suprema lex* is a saying that may be commended to the attention of politicians and others throughout the country.

Date of the Discovery of Alcohol.

The word alcohol originally bore no relationship to "aqua ardens" or "burning water," and to this confusion of terms is responsible all the uncertainty attendant on the date of the introduction of "spirit of wine" into history. The ancients knew of this inferentially and sought to extract it, but there has as yet been no evidence to show that these attempts met with success. We have, however, assurance that some of the ancient wines could ignite. Such wines must have been the native and unfortified—hence the mystery that some of them could respond to the flame test. We have heretofore been taught that wine was first distilled somewhere about the tenth century by Arabians, but know now that the latter must have obtained the process from Italians, and that no one knows how long the custom of distillation had been secretly pursued by the latter. In a recent number of the *Berliner klinische Wochenschrift* Paul Richter shows that a knowledge of "aqua ardens" may be traced as far back as the second century A.D. to one Hippolytus, a Christian Father, who possessed a recipe for the preparation of "burning water" entirely analogous to those handed about during the Middle Ages.

News of the Week.

Bender Laboratory.—The eighteenth anniversary of the founding of the Bender Hygienic Laboratory of Albany, N. Y., was celebrated on June 27 at a dinner given by the trustees of the institution. Among the speakers were Dr. Abraham Jacobi of New York and Drs. George Blumer of Yale University and Richard M. Pearce of the University of Pennsylvania, formerly directors of the laboratory. Dr. Harry S. Bernstein, the present director, also spoke on the activities of the institution.

Medical Class Gift.—The class of 1913 of the Tufts College Medical School has presented to Dean Charles F. Painter the nucleus of an endowment fund, each member of the class pledging himself to add a certain sum to the fund each year for as long as he shall live.

The New Laureate.—The post of poet laureate of England, left vacant by the death of Alfred Austin, is said to have been offered to Dr. Robert Bridges, who was for some years a practising physician in London. Dr. Bridges studied medicine at St. Bartholomew's, London, and was at one time a member of the staffs of the Children's and Great Northern Hospitals, but retired in 1882, when only forty years of age, to devote himself to literature.

Association for Cancer Research.—At the annual meeting of the American Association for Cancer Research on May 5, 1913, the following resolution, embodying the report of the Committee on Statistics and Public Education, was unanimously adopted: "It is the sentiment of the Association that: (1) The present instruction of medical students in the symptoms and early diagnosis of cancer is seriously deficient. (2) The medical curriculum

should include special lectures in the clinical departments dealing specifically with this subject. (3) The universities should provide competent lecturers in this subject to address the local medical societies. (4) The associate members of the Association should be urged to take up the question of the proper methods of approaching the public on the subject of cancer. (5) The activities of the Association should at present be confined chiefly to the education of the medical profession. (6) This resolution shall be sent to the deans of the medical schools and the secretaries of the State medical societies in the United States and published in the medical press."

Civil Service Examinations.—The New York State Civil Service Commission announces that examinations will be held on July 26, 1913, for the purpose of filling vacancies in the following positions in the State service:

Trained nurse in State institutions, open to men and women; salary, $420 to $600 and maintenance. Candidates must be graduates of a school registered by the State Education Department. This examination is intended to provide a list of eligibles for the positions of trained nurse, chief nurse, and hospital matron in State institutions, excepting the State hospitals for the insane.

Medical superintendent, Montgomery County Tuberculosis Hospital at Amsterdam, N. Y.; salary, $1,000 to $1,200 and maintenance. Candidates must be graduates of a reputable medical school, with at least six years' experience in actual practice of medicine, including one year of hospital work.

Dentist, resident in State institutions, open to men and women. Candidates must be graduates of a recognized dental school and eligible to enter the State licensing examination. A vacancy exists at the State Institution for Feeble Minded Children, Syracuse, at a salary of $50 per month and maintenance.

Applications for these examinations must be received in the office of the Commission on or before July 18, 1913, and blanks will be furnished before July 16 upon request to the State Civil Service Commission, Albany, N. Y.

School for Health Officers.—On November 1, 1913, a school for the training of health officers will be opened in Boston under the combined direction of Harvard University and the Massachusetts Institute of Technology. The administrative board will be composed of Prof. William T. Sedgwick of the Institute and Prof. M. J. Rosenau and Prof. George C. Whipple of the University. The new school is designed to meet the constantly increasing demand for properly trained health officers by supplying men who have a knowledge of both medicine and sanitary engineering and are fitted to occupy executive positions in this line.

Dr. Chao Choy, a Chinese doctor of the old school, who claimed to be 149 years of age, died on June 30 at Ellis Island, where he was being detained following his arrival from Cuba.

Ambulance Surgeon Injured.—In a collision between an automobile ambulance from the Lincoln Hospital, New York, and a heavy motor truck on July 3, the ambulance surgeon, Dr. Enrico Salvini, was thrown from his seat and sustained a fractured skull and internal injuries and both the driver and his assistant were severely hurt. The patient alone was not injured.

City Death Rate.—For the week ending June 28 there were reported in New York City 1,182 deaths, giving a death rate of 11.48 per thousand. The corresponding week of last year showed 1,233 deaths and a rate of 12.43 per thousand. For the first twenty-six weeks of the year the death rate was 15.04, while for the same period of 1912 it was 15.06. The infant mortality has shown a decrease also. During the week ending June 28, 1913, there occurred in the entire city 193 deaths of babies under one year of age, which was 29 less than in the same week of last year. In the Borough of Manhattan alone the number of infant deaths during the week fell from 124 in 1912 to 98 in 1913. For the first half of 1913 the infant death rate was 99.8 per thousand births, while for the same period last year it was 103.1, the difference representing a decrease of 75 deaths.

During the month of May, 1913, the infant deaths throughout the State numbered 1,826, which is a decrease of 183 as compared with the same month of 1912.

Hospital Cornerstone Laid.—On June 30 the cornerstone of the new Volunteer Hospital at Beekman and Water streets, New York, was laid with appropriate ceremonies conducted by the Volunteers of America. It was stated that since June, 1905, when the present building was opened, the total number of treatments has reached 382,283, and that the new building will largely increase the facilities.

The Friedmann Vaccine Again.—At a meeting held on July 1, the Board of Health of New York City adopted a resolution, of which the following is the substance, for the purpose of controlling the administration of the Friedmann vaccine for tuberculosis in this city: The injection or treatment of human beings within the City of New York with the F. F. Friedmann "vaccine" (which contains living bacterial organisms) is prohibited except under the following regulations and restrictions: No persons may be treated, according to the foregoing, who did not receive one or more treatments with the same kind of living bacterial organisms in New York City previous to May 30, 1913. These treatments may be administered only in the following-named hospitals: Bellevue Hospital, Mount Sinai Hospital, Montefiore Home, and Seton Hospital and any other that the Board of Health may approve. No person may be so treated until he or his parent or guardian, in case of a minor, has signed a declaration in duplicate stating that he desires these treatments continued. One copy of each of the above declarations must be filed with the Department of Health on or before the day such treatment is administered and the other copy retained by the physician who administers the treatment. This physician must also file in the Department of Health a statement of the dose given and the method of its administration and the hospital in which it was given in each case within forty-eight hours after treatment. The Berlin Medical Society has dismissed the subject of the vaccine as unworthy of discussion at its meetings. A committee of Pittsburgh physicians has studied the effects of the turtle bacillus in the human subject and declares that the treatment is not of sufficient value to warrant an abandonment of the approved methods now in use. A committee appointed by the Canadian Association for the Promotion of Tuberculosis has reported that nothing has been found in their investigation to justify any confidence in the alleged remedy. Finally Drs. Wolff-Eisner, Joachimsthal, and Kraus appointed by the New York *World* to

study the vaccine and report upon its value, have cabled from Berlin that they can obtain no material whereon to base an opinion.

Dr. G. G. Rambaud in a letter to the MEDICAL RECORD, after referring to Friedmann's policy of secrecy, says that he (Dr. Rambaud) has now concluded that "the medical profession is entitled to know that the vaccine is simply a homogeneous emulsion of live avirulent tubercle bacilli in plain sterile distilled water. The germ was isolated several years ago from a turtle and the culture has been maintained since that time by transplantation on artificial culture media, according to the usual procedure." What the vaccine is has been known from the beginning, although Friedmann to the last endeavored to make a mystery of it; but the claim that the bacilli are non-virulent and harmless has not been sustained either in Berlin or New York.

Knickerbocker Hospital.—The J. Hood Wright Memorial Hospital of New York recently obtained from the Supreme Court permission to change its name to the Knickerbocker Hospital. It is believed that the present name has led to the false impression that the hospital is an endowed institution, and that therefore the necessary public financial support has not been forthcoming. Since the death of Mr. Wright the population of the district served by the hospital has increased enormously and the need of funds for the work has become proportionately greater.

Rockefeller Institute.—The Board of Scientific Directors of the Rockefeller Institute for Medical Research announces the following changes in the staff: Promoted from assistant to associate, Frederick B. La Forge, Ph.D. (chemistry), James B. Murphy, M.D. (pathology and bacteriology); Gustave M. Meyer, Sc.D. (chemistry), and Martha Woollstein, M.D. (pathology and bacteriology). Promoted from fellow to assistant, Michael Heidelberger, Ph.D. (chemistry). New appointments: Wade Hampton Brown, M.D., associate in pathology and bacteriology; Carroll G. Bull, M.D., assistant in pathology and bacteriology; Frederick Lamont Gates, M.D., fellow in physiology and pharmacology. The following appointments in other institutions of former members of the staff have also been announced: Dr. G. Canby Robinson, formerly associate in medicine, has been appointed associate professor of medicine at Washington University, St. Louis; Dr. Jacques J. Bronfenbrenner, formerly assistant in pathology and bacteriology, has been appointed director of the pathological laboratory of the Western Pennsylvania Hospital, Pittsburgh, and Dr. Richard Vanderhorst Lamar, formerly associate in pathology and bacteriology, has been appointed professor of pathology at the University of Georgia. Dr. Wilfred Hamilton Manwaring, formerly assistant in pathology and bacteriology in the Rockefeller Institute, has been appointed professor of bacteriology and immunity at Leland Stanford Junior University, San Francisco, Cal.

Gifts to Charities.—By the will of the late Margaret E. Mitchell of New York, the Roosevelt Hospital receives a bequest of $1,500 and the Presbyterian Hospital one of $1,000.

By the will of the late Miss Ellen Collins of New York $5,000 is bequeathed to Lebanon Hospital, Syria, and $1,000 to the Lincoln Hospital of this city.

By the will of the late Jane McKee Norris of Philadelphia the sum of $50,000 is bequeathed to the Presbyterian Hospital and $5,000 each to the Benevolent Fund of the Ladies' Aid Society of the Presbyterian Hospital and the Home of the Merciful Saviour for Crippled Children.

St. John's Guild receives $5,000 and the Association for the Aid of Crippled Children $10,000 by the will of the late Mr. Charles Kohler of New York.

Dr. Fenton B. Turck has removed from Chicago to New York, at 14 East 53d street. The research laboratory conducted by him, which has been endowed by two of his former patients, has also been transferred to this city, at 428 Lafayette street.

New York State Board of Medical Examiners.—Dr. Earl H. King of Saratoga Springs, and a graduate of the New York Eclectic Medical College of the year 1898, has been appointed Examiner in Pathology in place of Dr. Lee H. Smith who declined reappointment.

Medical Society Elections.—At the annual meeting and banquet of the BELKNAP COUNTY, N. H., Medical Society, held on June 16, the following officers were elected: *President,* Dr. Benjamin W. Baker, Laconia; *Vice-President,* Dr. L. B. Morrill, Centre Harbor; *Secretary-Treasurer,* Dr. Clifton S. Abbott, Laconia.

The TRI-COUNTY MEDICAL ASSOCIATION OF OHIO, comprising the counties of Seneca, Wood, and Hancock, at its annual meeting in Findlay on June 26, elected the following officers: *President,* Dr. Robert Lee, Republic; *Secretary,* Dr. E. H. Porter, Tiffin; *Treasurer,* Dr. George L. Hoege, Fostoria.

The LAKE COUNTY, ILL., MEDICAL SOCIETY held its annual meeting June 26 at Libertyville, when the following officers were elected: *President,* Dr. W. S. Bellows, Waukegan; *Vice-President,* Dr. E. V. Smith, Libertyville; *Secretary,* Dr. W. C. Bouton, Waukegan.

Obituary Notes.—Dr. FRANCIS LORING BANFIELD of Worcester, Mass., a graduate of the Medical School of Maine, Portland, in 1881, and a member of the American Medical Association and of the Massachusetts State and Worcester District Medical Societies, died at his home from angina pectoris, after a long illness on June 25, aged 69 years.

Dr. J. HOWARD LEVER of Flushing, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1869, and for fifteen years health officer of the town of Flushing, died suddenly at his home on June 25, aged 66 years.

Dr. GEORGE W. ROBINSON of Newark, N. J., a graduate of the New York University Medical College in 1863, a surgeon in the United States Army during the Civil War, and for many years a practising physician in New York City, died at his home on June 22, aged 70 years.

Dr. HERMAN L. ESSEX of Hope, Ind., a graduate of the Kentucky School of Medicine, Louisville, in 1902, died at his home from pulmonary tuberculosis, after a long illness, on June 19, aged 38 years.

Dr. J. E. JONES of De Soto, Mo., a graduate of Rush Medical College, Chicago, in 1871, and formerly coroner of Jefferson County, Mo., died at Williamburg, Ia., on June 19, aged 67 years.

Dr. C. GEORGE BULL of Alameda, Cal., a graduate of the Bellevue Hospital Medical College, New York in 1881, and a member of the American Medical Association and the California State and Alameda County Medical Societies, died suddenly while

on a fishing trip at Big Meadows, on June 20, aged 54 years.

Dr. H. E. Morrison of Medford, Ore., a graduate of the Vanderbilt University Medical Department, Nashville, in 1900, and a member of the Oregon State Medical Society, died in the Sacred Heart Hospital, Medford, following an operation for appendicitis on June 20, aged 37 years.

Dr. Herbert Skelton Carter, formerly of New York, a graduate of the College of Physicians and Surgeons, New York, in 1872, died suddenly at his home in Tarrytown, N. Y., from angina pectoris, on July 2, aged 64 years.

Dr. John G. Weber of New York, a graduate of the University of Jena, Germany in 1865, died at his home on July 2, aged 70 years.

Dr. Frank H. Boynton of New York, a graduate of the New York Homeopathic College in 1874, a member of the American Institute of Homeopathy and of the New York State Homeopathic Medical Society, and senior surgeon at the New York Ophthalmic Hospital, died suddenly at his summer home in Mount Washingon, Mass., aged 62 years.

Dr. Gustavus P. Head of Chicago, Ill., a graduate of Rush Medical College, Chicago, in 1884, a member of the American Medical Association, the Illinois State and Cook County Medical Societies, the American Academy of Ophthalmology and Oto-Laryngology and the Chicago Laryngological and Otological Society, professor of otology, laryngology, and rhinology in the Post-Graduate Medical School of Chicago, and general editor of *Practical Medicine,* died at his home on June 11, aged 51 years.

Dr. Ambrose H. Weeks of Portland, Me., a graduate of the Medical School of Maine, Portland, in 1893, a member of the Maine State and Cumberland County Medical Societies, and but recently appointed assistant professor of gastro-enterology in the Medical School, died at his home from typhoid fever, aged 43 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

RESEARCH ON PATHOLOGY OF POLIOMYELITIS AND ALLIED AFFECTIONS—DISTRICT NURSING IN LONDON—THE LATE DR. DABBS—RESEARCH DEFENCE—INSURANCE—OBITUARY.

London, June 20, 1913.

Dr. R. G. Rows and Dr. David Orr have made careful researches respecting the mode of development of acute myelitis, and some of their experiments tend to explain the pathology of poliomyelitis and similar conditions. It was known that toxins could pass by the lymph streams of peripheral nerves into the central nervous system, and that degeneration of the myelin sheaths in their course might follow. But the experiments described at the late quarterly meeting of the Medico-Psychological Association by Drs. Row and Orr carry this a step further. Capsules containing organisms were sutured against the dura at the level of the lumbosacral enlargement, in some close to an intervertebral foramen. Positive results were obtained in all experiments, the irritation to the nervous and meningeal tissues being less marked from without inwards, the minimum being near the central canal of the cord. Plasma cells were found in quantity all along, cellular infiltration in veins only. The dura mater seemed to prevent the passage of organisms. Yet pathological changes were found in both the white and gray matter of the cord, its vessels being dilated, infiltrated with round cells, or thrombosed with acute degeneration in the nerve cells of the gray matter. The phenomena were so like those of acute poliomyelitis as to suggest this must be a lymphogenous infection. In all the experiments the authors found a collection of plasma cells and polyplasts at the proximal end of the posterior root ganglion, suggesting special reaction at that spot which might be a defence against further upward extension of toxins or organisms.

The president (Dr. Soutar) extolled the painstaking work of the authors which proved the view he had always maintained that this country was second to none in original research.

In reply to some questions, Dr. Rows said the pneumococcus could certainly pass through the placenta, for it had been found in the fetus. Their paper was meant to show that toxins reached the lymph stream from nerves adjacent to the affected nerves. In tabes there was no infiltrative reaction but a degenerative change. In acute specific febrile conditions, or, at any rate, in some of them, the toxins spread from the mucous membranes.

There was an informal conference at the Local Government Board on Saturday of ladies and gentlemen interested in district nursing in London. Most of the institutions connected with this work were represented, as may be said, also, of the medical profession, for Sir Wm. Church, Sir Pearce Gould, and Sir T. Barlow were among those who had accepted the invitation.

Mr. John Burns, as president of the Local Government Board, thanked them for their attendance, and explained that this conference was only one of a series of efforts of the Board to link up the different agencies, both public and private, which were working for the benefit of the poor. The best results in nursing, he thought, had not been obtained, and that partly owing to the want of cooperation. Recent legislation had greatly altered the problem. There had been a great extension of medical service in the way of inspection of school children and visiting them in their homes. The feeding of them was to some extent connected with district nursing. Dispensaries and sanatoria bore more or less on the matter. It was certain that some districts were well provided with nurses, while in others the poor were often obliged to do without the help they sadly needed. He feared that much philanthropy and devoted service were at present running to waste. As chief of the central public health authority he welcomed the conference of those who had done much already for the poorest citizens, and were now willing to consider what improvements were practicable. There were 400 women engaged in this nursing, at a cost, he was told, of only £30,000, and no money was giving better returns. Guardians had power to subscribe to nursing associations. Old age pensioners formed a new class who would be greatly benefited by the occasional visit of a district nurse.

It was only right that these old people should remain in their homes as long as they could, instead of going into infirmaries. Mr. Burns said there was no desire to interfere with the management of any society, but he thought there should be unification and coordination of aim in order to prevent waste of money, time, energy and devotion. He desired, if possible, a permanent committee as a

center for different agencies to coordinate their work. As an instance of good results of such procedure, he instanced the Notification of Births act, which brought the working class mother into touch with all kinds of philanthropic agencies, and had diminished infant mortality from 145 to 90 per 1,000 births. The quality of the nurses had greatly improved; it was not necessarily medical or surgical. Their great value was their sisterly or neighborly visits to the homes of the poor. They talked to them, not at them, and by kindly advice and persuasion brought about changes in their homes for the better.

After some discussion it was resolved that a committee of ten be formed to promote a scheme of closer cooperation between the bodies concerned in district nursing in London and to report to a later conference. A provisional committee of ten was thereupon appointed with power to add to their number.

The coroner's inquest on Dr. Dabbs, whose death I mentioned last week, revealed a touching story of his sufferings which drove him on many occasions to inhale chloroform, of which he evidently took an overdose. He left a sort of diary, written on the back of a number of envelopes. This points to a long series of attacks of angina. An early entry was that "this experience will perhaps explain what must happen some day—no one is to blame." Later, "pain down left arm agonizing; chloroform might relieve." Succeeding notes tell that pain was "quenched two half hours," "coming back," "spite of promise, shall take more chloroform, but am bound to stop it or it will stop me." Some days later he wrote, "avoided morphia hitherto, but the pain is too much, and chloroform like milk to me, but I do so want to live." Other notes refer confusedly to passing views and kind words to his friends. They seem to grow more confused and indistinct. What seems to be the last reads, "Can I keep awake till they find me—find me—find me—I must." The inquest terminated in a verdict of misadventure. The medical evidence had ascribed it to syncope, accelerated by chloroform.

The owner of premises let to one of the antivivisection societies for a month has presented the rent received (£30) to the Research Defence Society.

There is much talk about the promised bill for amending the insurance act, but scarcely any one seems to expect anything to be done to favor the profession. The work of those on the panel is described to me as impossible to do satisfactorily.

Dr. Julius Lawrence Hamilton, who died suddenly of cardiac failure in his sixty-ninth year, deserves the name of the fisherfolk's friend. He wrote much about fish and fisheries, including reports on the fish markets and fish supply of the metropolis to the London County Council. He was the originator of Fisherfolk's Naval and Cadet Reserves and of free technical schools for them. He seems to have had some engineering tastes too, for he invented automatic appliances for bread making and cooking, improved pyrometers and dry-air refrigerating cars.

Fleet-Surgeon F. R. M. Loftie died on June 14. He qualified L.R.C.P. 1871 and entered the Naval Medical Service the following year, from which he retired in 1896. He has since been a justice of the peace for Armagh and Down counties.

The death is reported of Dr. Wm. Hy. Langley, C.M.G., P.M.O. of Southern Nigeria, F.R.C.S.I. He was at one time assistant surgeon of the Richmond Hospital, Dublin, and in charge of the Ordnance Survey. He served in Borger and the Kontagoro expedition, being mentioned in dispatches and awarded medals and clasps, and later in the Kano and Sokoto operations. Subsequently he was deputy P.M.O. in Northern Nigeria, P.M.O. of the Gold Coast Colony, and in 1911 of Southern Nigeria.

News has arrived of the death of the professor of physiology (Dr. Nathaniel Hy. Alcock) at Montreal. He was a highly distinguished graduate of Trinity College, Dublin, M.D. 1896, and was assistant professor there 1898 to 1902. In 1904 he became lecturer on physiology at St. Mary's Hospital, London, and in 1911 went to McGill University, remaining there until his death at the age of 42. He wrote a number of papers on his subject and was co-joint author with Dr. Ellison of a manual of experimental physiology.

OUR CANADIAN LETTER.

(From Our Regular Correspondent.)

MEETING OF THE CANADIAN MEDICAL ASSOCIATION AT LONDON, ONTARIO.

The forty-sixth annual meeting of the Canadian Medical Association was held in the Masonic Temple, London, Ont., from June 24 to 27, 1913. London, although not so well provided with facilities for holding a medical meeting as the city of the same name on the other side of the Atlantic, yet in some respects is a more pleasant place for such a gathering than the smoky British metropolis. In the first instance the weather was sultry in the extreme and the Canadian London is beautifully shady and quiet and restful. This is not to say that it is not a busy center of industry, for it is, but it is not noisy and dusty like the old London and the road in which the Masonic Temple is situated is lined with fresh green lawns and protected from the rays of the sun by trees heavy with foliage.

The inhabitants of London, too, did their utmost to make the stay of the visitors enjoyable, and in this attempt succeeded excellently well. A repast was given by the Hydro-Electric Company at their lovely park, Springbank, and the hospital authorities provided a lunch at the fine Victoria Hospital. There were smokers, garden parties, and so on, and from the social standpoint everything passed off without a hitch.

From the medico-scientific standpoint the meeting was also a success. The papers were good in quality, and except, perhaps, that the program was somewhat too lengthy, the meeting from every point of view fulfilled expectations. In making this statement, however, certain reservations, or, at any rate, one reservation must be made, the attendance of members was disappointing. The registration was not up to the desired standard and, considering the attractions of London and that it is well served by railroads, this is to be wondered at.

Taking the proceedings in order, not exactly the order of the program, the address of the President, Dr. H. A. McCallum, may first be considered. The president delivered an aggressive critical address. He deplored the apparent lack of interest in the association exhibited by the mass of the Canadian medical profession and called attention to the necessity for funds to rescue its members from the

exploitation by and the commercial enterprise of certain drug houses. It was pointed out that the chemical industry of Germany was carefully organized and it was difficult to know what to accept and what to reject. Trained and scientific censors were needed to give advice and to assist in shaping legislation to prevent the sale of nostrums. Qualified praise was accorded to the work of the Carnegie Foundation, for while it was allowed that its report had been instrumental in the removal of many abuses, at the same time criticisms were leveled at its conclusions that the German methods of medical education and training were the best. Dr. McCallum is one of those who believes that the British methods are those best adapted to turn out good practical medical practitioners, which after all is the object to be aimed at. The annual examination by competent physicians of every adult was urged. Insurance companies had adopted a plan of examining their clients annually, and in the opinion of the speaker it would be of benefit to all concerned if this example were followed generally. Attention was drawn to the overburdened curriculum of the medical student, who was now asked to digest and assimilate an unconscionable variety of indigestible material. Dr. Lewellys Barker, Professor of Medicine at Johns Hopkins University, and himself a Canadian, delivered the address in medicine. It dealt with the nerve supply of the internal secretory organs and the smooth muscles, and was, of course, illuminative in a high degree. It was not a real address, but given in the manner of a lecture, the lecturer illustrating his points by means of pictures thrown on a screen. As the lights were turned out it was impossible to take notes. Later on the address will be published in the *Journal of the Canadian Medical Association*, so that medical readers will have the opportunity to peruse the presentation of an original subject sketched by a master hand.

The address in surgery was given by Dr. J. Alexander Hutchison of Montreal, and the subject discussed was the treatment of fracture. Dr. Hutchison reviewed exhaustively and ably the history of the treatment of fracture and referred in laudatory terms to the work of the commission appointed by the British Medical Association to investigate into and report on the matter. He also gave high praise to the part of a report published recently by American surgeons on the treatment of fracture. Perhaps the portion of the address which aroused the greatest amount of interest and certainly struck a sympathetic chord in the breasts of his listeners was that which dealt with the need of the status of medical men to be defined by law, with regard to suits for malpractice. He pointed out that since the introduction of radiography into medicine and surgery skiagraphs of fractures were made use of frequently in courts of law to the detriment of the profession. "No layman nor lawyer is competent to say whether or not the photograph is a true picture of conditions. They do not know the pathological aspect of the case. Experts alone should decide. We should be protected from such practice. The question of medical ethics is also involved, for I do not see how it is that any physician can sell radiographs to injure a brother physician." With all this, it is needless to state, those present were in hearty agreement.

Dr. T. S. Cullen of Johns Hopkins University, who, like Dr. Barker, is a Canadian, gave an address in gynecology. While the address was termed an address in gynecology, it was rather an earnest and eloquent plea for the adoption in Canada of the methods used in the United States for the purpose of familiarizing the general public and especially women with the early symptoms of cancer so that they may be able to take steps in time to eradicate the disease, or at least to stay its spread. Dr. Cullen gave a most instructive description of the means employed in America to reach the desirable end. He said in part that it was decided by those responsible for the inception and prosecution of the campaign to use the lay press and magazines as the medium for the dissemination of knowledge regarding the detection of the early symptoms of malignant disease. It was further decided that a medical writer would not be called upon to do the main part of this work, but a lay writer who had demonstrated the possession of peculiar gifts for presenting a subject medical or otherwise with clearness to the general public. It was Mr. Samuel Hopkins Adams who had been hired to do this work.

The speaker was insistent upon the point that women in particular should be influenced in this direction not only because women are more prone to malignant disease but because if women can be induced to recognize the necessity for having a diagnosis of cancer made early the men will readily follow suit. "The woman is the health guardian of the home."

It was pointed out that cancer of the stomach was a prevalent disease, but very difficult to diagnose in the early stages. An exploratory operation was the best method of arriving at a definite conclusion and in many cases already recorded this mode of procedure had been attended by satisfactory results.

The speaker emphasized the importance of the pathologist in making diagnoses and said that in the future every hospital would have a surgical pathologist on its staff. The necessity for having such a man was becoming more apparent every day. The great surgeon of the future would also be a great pathologist. The adoption of business methods in the operation of hospitals was discussed and highly commended, and in concluding his paper Dr. Cullen strongly urged the medical association of Canada to seriously consider the advisability of inaugurating a campaign against cancer on similar lines to that now being waged in the United States. It will probably be remembered by readers of the MEDICAL RECORD that it was stated in the Canadian letter some six weeks or so ago that a committee had been appointed in Canada to investigate the so-called Friedmann cure. After a long and patient investigation the committee handed in its report at the meeting of the Canadian Medical Association. Dr. J. George Adami, one of the committee, made some preliminary remarks, sketching the history of the events leading to the report, and then Dr. George Porter of Toronto read the following: "In order to allay public excitement and to afford to the medical profession and the people of Canada an authoritative statement regarding the value of Dr. Friedmann's treatment the Canadian Association for the Prevention of Tuberculosis nominated a committee of five members to study and report upon cases inoculated by Dr. Friedmann at Montreal, Ottawa, Toronto, and London. That committee has added to itself those physicians who have had under their observation the cases treated in these cities. The committee thus constituted begs to report that it has carefully studied the case histories of the patients inoculated by Dr. Friedmann. These num-

ber in all 116, namely: For Montreal, 10; for Ottawa, 10; for Toronto, 81; for London, 15. As a result of our observations from March 11 to the present time the following conclusions seem justifiable: 1. The inoculations have neither constantly nor frequently been followed by marked change in the clinical course of the disease. 2. The cure or progress towards recovery claimed by Dr. Friedmann for the treatment has neither constantly nor even frequently taken place in the time during which these cases have been under observation. 3. Thus, upon investigation, the committee finds that the results have been disappointing and that the claims made for his remedy by Dr. Friedmann have not been proved, and that nothing has been found to justify any confidence in the remedy. (Signed) Professor J. George Adami, Professor J. J. Mackenzie, Dr. A. H. Caulfield, Dr. G. S. Harding, Dr. John W. S. McCullough, Dr. W. Ross, Dr. J. H. Elliott, and Dr. George Porter.

Dr. Charles H. Hodgette, a member of the committee, being averse to making any report, did not sign. According to a London paper Dr. Hodgette held that Dr. Friedmann had so thoroughly discredited himself by failing to keep the promise he made that he would reveal the composition of the remedy to the members of the committee, that he thought it was useless to make public a report.

Thus Dr. Friedmann seems now to have failed as egregiously to prove his assertions in Canada as he has failed in the United States. At any rate, no one can say now, with any truth, that he has not had a fair field and honest treatment.

OUR BERLIN LETTER.

(From Our Regular Correspondent.)

THE INTERNATIONAL CONGRESS OF PHYSIOTHERAPY—NATURAL IMMUNITY AND NUTRITION—EXCESS OF CARBOHYDRATES DIMINISH RESISTANCE TO TUBERCULOSIS—ALCOHOL IN RELATION TO INFECTIOUS DISEASES—DIET IN SEVERE CASES OF DIABETES—DANGERS OF PROTEIN DISINTEGRATION AND OF ACIDOSIS—CARBOHYDRATE DIET IN SEVERE DIABETES—THE DIETETICS OF GOUT—COFFEE AND URIC ACID—DIET AND NEPHRITIS.

BERLIN, May 15, 1913.

THE Fourth International Congress of Physiotherapy was opened with great enthusiasm in the Reichstag March 26. The following day there were presented an extraordinary number of interesting papers of which only a few can be mentioned in this letter.

Czerny, of Berlin, spoke of the dependence of natural immunity upon nutrition. Being the successor of Heubner in the pediatric chair of the University of Berlin Czerny discussed this subject chiefly with reference to childhood. The well-fed infant at the breast has considerable resistance to disease; for example, it is not subject to thrush. The slightest disturbance of nutrition impairs immunity. Mother's milk rich in fat imparts to the infant a high degree of immunity, while a preponderating carbohydrate diet diminishes immunity. It is necessary to add to such diet fat in the form of cod-liver oil. Even in animal experiments it has been noted that an overwhelming carbohydrate diet diminishes the resistance to tuberculosis. The excess of water in the diet diminishes natural immunity. Children made puffy by excessive drinking of water have slight resistance to infection, chiefly tuberculosis, which in these children has a tendency to spread rapidly. A deficiency of lime in the diet causes an excess in the potassium and sodium salts, which favors edemas. The fat of cow's milk by the formation of calcium soaps can hinder the absorption of calcium. This may result in a deficiency in alkalies and the onset of acidosis which may seriously affect the organism. Such variations in the alkalinity favor the incidence of infectious processes.

The relation of alcohol to infectious diseases was discussed by Ewald, of Berlin. He came to the conclusion that in no infectious disease has the value of alcohol been proved. This substance lowers the natural resisting power of the organism and influences unfavorably the blood pressure and respiration. In most hospitals the consumption of alcohol has very properly been considerably diminished. In the hospital supervised by the speaker alcohol is given only on the physician's orders. During the past nine years the consumption of wine has diminished one-half. Alcohol is ordered only for two conditions: in severe cardiac collapse of toxic or mechanical origin or in diabetes mellitus, and as a means of producing euphoria in hopeless cases of disease.

The diet in severe cases of diabetes with special reference to acidosis was a subject presented by three speakers: von Noorden, of Vienna, Labbé of Paris, and Blum of Strassburg. Von Noorden differentiates among the severe cases of diabetes the benign from the malignant form. In the latter there is little of therapeutic value, but the patients do best on 75 to 120 grams of bread daily with the intercalation for short periods of "vegetable" days, "oatmeal" days, and fasting days. The benign cases are characterized by the fact that with careful treatment the course may be a favorable one. In these cases the estimation of carbohydrate tolerance may be more exactly made. It is possible to determine not only the quantity of carbohydrate that may be assimilated, but also whether this can be taken at once or in different portions, whether this tolerance varies on different days, and whether it is affected by rest or work. A rigid diet carried out for months is indicated even in those cases in which the patients at times lose flesh, but in these cases the exercise of good judgment and culinary skill may be helpful. Nephritis resulting from a strict diet is not to be feared. Of importance in these cases are occasional oatmeal days following days of a vegetable and egg diet. One vegetable day at least should follow the oatmeal days. In other cases it is not possible with an ample diet to make the patient permanently free of glycosuria. Such patients are to be kept on a rigid diet provided that a high degree of acetonuria does not result. In this instance there is often necessary a variation in the diet, in which a strict regimen of 50 to 80 grams of carbohydrate is interrupted by periods of carbohydrate-free days, and days of a fatty and vegetable diet. In the severe types of disease alcohol is of extraordinary value. In threatening coma the administration for a few days of from 150 to 200 grams of diluted cognac is of eminent value. Mineral-water cures have no influence on the diabetic process, and are of distinct danger in causing subsequent carelessness in carrying out the recognized measures with treatment.

Labbé went more deeply into the subject of the dangers of protein disintegration and of acidosis. The most active is a mixed diet of meat with lim-

itation of carbohydrates. This regimen counteracts the hyperglycemia and the protein decomposition but leads to acidosis. A milk diet, cereal cures, and legumes counteract the acidosis and increase the hyperglycemia. Bearing these principles in mind it is necessary to formulate for each case a definite diet chart.

Bing discussed more particularly the subject of carbohydrate diet in severe diabetes. The glycosuria need not be appreciably increased, but should rather be diminished with this diet. The same is true of the acidosis. In the oatmeal cure there should be given of this cereal to patients without any great tolerance from 100 to 150 grams. Wheat, oatmeal, and barley flour have the same effect in the diet; they may be given in the form of a gruel or of a soup. If the cereal diet is unsuccessful it should be repeated several times at intervals. If there is accompanying disease of the heart, kidneys, or liver, a short milk cure is of advantage.

The dietetics of gout was a subject presented by Minkowski of Breslau and Garrod of England. Minkowski pointed out that with the exclusion of foods that lead to the formation of uric acid the therapeutic problem was not entirely solved. The diet must be adapted to the needs of each case. In practice the following articles of food are to be regarded as purin-free: eggs, caviar, bread, potatoes, and rice. Legumes contain as much purin as meats. A liter of beer because of its content in yeast yields as much uric acid as 100 grams of meat. Tea and coffee do not produce uric acid.

Garrod prefers a diet poor in purin bodies to one absolutely devoid of these. A one-sided diet cannot be kept up long without harm to the organism. The practical results of the dietetic treatment of gout have been generally overestimated.

In the discussion of the dietetic management of nephritis, Jancvski of Kiev stated that his investigations have not shown any harm resulting from the use of dill, parsley, and pumpkin, but the effect of vegetables in general requires further study.

2. Cerebral Complications of Pneumonia.—C. F. Withington points out that it is important to recognize clinically that in a few cases pneumonia may be complicated by cerebral symptoms, which may be, on the one hand, either those of grave organic lesion, of which the commonest is meningitis, or, on the other hand, of apparently toxic origin with little or no destruction of brain tissue. The enormous prognostic importance of this distinction is evident, but the difficulty in diagnosis is sometimes insuperable. Lumbar puncture is of importance in excluding meningitis, though it is not an unfailing criterion. Examination of the fundus may be useful. Cases of encephalitis are not always to be distinguished from the functional cases, and it is possible that many cases of hemorrhagic encephalitis may recover. The prognosis, if one be assured of the inorganic toxic character of the disease, would be on the whole favorable, though it is not as roseate as is indicated by some of the authorities. The occurrence of the cerebral symptoms in a young healthy person is more suggestive of a toxic functional character than would be the case in aged people. The toxemia is productive of diverse symptoms according as its incidence is upon the central or the peripheral nervous system.

4. Bulbar Paralysis in Typhoid Fever.—R. Fitz, F. G. Brigham, and J. J. Minot conclude that, on the whole, acute bulbar paralysis must be recognized as being a rare complication of typhoid fever. The symptoms usually suggest at the onset an acute ascending paralysis, developing either at the height of the disease or after convalescence has begun, and ending with evidence of bulbar involvement. Recovery may take place after a prolonged illness, or death may occur within a few hours. The varying pathological findings show that such a clinical picture may exist without evident tissue change in the nervous system or may be due to peripheral nerve lesions, or to a hemorrhagic encephalitis analogous to that found in other forms of infection, or finally to the presence of organisms in the brain, whether typhoid bacilli or secondary invaders, in sufficient numbers to cause the symptoms encountered.

1. Surgical Treatment of Cancer.—By J. A. Hartwell. (See MEDICAL RECORD, April 26, 1913, page 773.)

2. Treatment of Infected and Ununited Fracture of the Shaft of the Femur.—R. C. Turck alludes to Royal Whitman's emphasis on the necessity of fixation in abduction in the treatment of fracture of the neck of the femur. In fracture of the upper third of the femur the necessity for fixation or traction in abduction is practically as great as in fracture of the neck, since the powerful fibers of the gluteus medius and gluteus minimis readily overcome the upper fibers of the abductors; the result being that the upper fragment is always in abduction and cannot be drawn down to a straight line by an amount of direct traction upon the lower limb that can be borne by the patient for a long period of time. Indeed, a moment's consideration of the musculature of the thigh should convince one that a direct pull downward on the lower limb scarcely affects the position of the upper fragment, since the bulk of the resistance to the direct pull is borne by the hamstring muscles, the abductor longus, and the rectus femoris, all having their origin from the pelvis, not from the upper fragment. That portion of the quadriceps attached to both upper and lower fragments is entirely insufficient to neutralize the powerful outward pull of the abductors. If the principle of fixation or traction in abduction were more generally followed one would have less of shortening and outward deformity following the treatment of femoral fracture by the closed method, and there would be fewer cases demanding operative correction with the possibility of adding infection to deformity.

3. Surgical Luck.—J. D. Whitall states that surgical luck, *per se*, does not exist. It may, however, be acquired by returning to the fundamentals, the simplest things being often the best. One should acquire the small details of asepsis, exercise common "horse sense," work with the same assistants, eliminate needless risk, prevent shock, and rule out unnecessary postoperative meddling, thereby giving the patient a *chance* to get well.

4. Preventive Medicine in Relation to Psychiatry.—

J. G. Fitzgerald believes that each hospital should concern itself with the mental health of its local community. Public lectures on methods to prevent the development of mental disease should be given. The factors underlying the development of insanity should be explained, if possible, to the friends and relatives of patients, in the hope that further cases may not arise from the same source. Explanation of the importance of syphilis, alcohol, and heredity taint in the production of insanity should be offered. The tide should be turned back as far as possible, in just the same manner as in the infectious diseases. Preventive medicine in psychiatry is as necessary as in any other field. The requisite effort can be made only by an intelligent utilization of the machinery already at our disposal.

9. **Myomas of the Stomach.**—C. B. Farr and R. A. Glenn note that benign neoplasms of the stomach, though rare, show a great variety of forms. Epithelial growths, adenomas, etc., are scantily represented, but connective tissue tumors of almost every type occur—lipomas, fibromas, myomas, and even chondromas and osteomas. Angiomas and cysts are found occasionally, but the latter in particular usually result from degenerative changes in myomas. Lymphomas occur in leucemia; lymphadenomas and endotheliomas are classed with malignant growths. Many of these benign tumors show a tendency to take the form of polyps—in some forms of chronic gastritis a general polypoid hypertrophy of the mucous membrane takes place, but the minute formations that result can hardly be classed as tumors from a practical standpoint. Myomas are the most important of the benign tumors with reference both to their frequency and to the symptoms to which they give rise. They are also important on account of their tendency to undergo sarcomatous degeneration.

1. **Auscultation of Early Pathological Changes in the Lungs.**—H. Sewall concludes that auscultation is capable of giving the earliest objective information of physical changes in the lungs. Such study demands analysis of the sound into those vibrations due to resonance of the viscera and those of the chest wall, and that the latter vibrations can be damped by pressure of an appropriate form of stethoscope. Vibrations transmitting the whisper are confined almost wholly to the viscera. The modifications of the voice sounds by which their quality becomes more amphoric and their duration prolonged into an echo are the striking characters which when accentuated by stethoscopic pressure indicate pathological changes in the viscera. The character and distribution of vocal signs over the normal chest are sufficiently constant so that a topographical study of the chest by auscultation may definitely suggest, through recognition of departures from the normal, the intensity and distribution of morbid changes within the lungs, even when these changes are too slight to appeal to the senses through any other method.

3. **New Operation for Indirect Inguinal Hernia.**—U. C. Bates describes a new method of operating for indirect inguinal hernia. An incision about two inches long is made parallel with Poupart's ligament, its end about an inch above the usual location of the internal ring. The fascia of the external oblique is divided in the line with its fibers. The arching fibers of the internal oblique are separated and retracted, and the fascia of the transversalis together with the peritoneum is opened. Any adhesions can be broken up by traction and blunt dissection with the finger. The internal ring, including the neck of the sac, is caught up with an Allison tissue-forceps or a hemostat and pulled up to the incision, where a purse-string suture of No. 3 plain catgut, on a needle, is passed around the circumference of the ring, engaging the fascia of the transversalis except at the junction of the inner and lower quadrant, where the vas deferens or round ligament is encountered; this is excluded externally from the ligature. Pulling up the internal ring and transversalis fascia restores them to the original position held before a hernia was produced. The purse string is drawn taut, tied, and the same suture is passed from within through the parietal peritoneum and through some of the fibers of the internal oblique muscle. It is then passed from without inward through the muscle and peritoneum of the opposite side of the incision, where it is tied to the free end of the purse string. The next stitch is then passed through the peritoneum, then through what is now the superior portion of the ring. When this is drawn tight it faces and holds the ring firmly against the parietal peritoneum. The remainder of the peritoneal incision is closed by a continuous stitch with the same suture. The remainder of the wound is then closed in the usual manner. The operation has been performed in six cases and in no case has there been a recurrence. The advantages claimed are its simplicity, the smaller incision required, the restoring the inguinal canal in an oblique direction by drawing the internal ring to its normal position and so directing the intraabdominal pressure as to render the recurrence of rupture impossible. There is also a better chance for making resection, if necessary, in case of strangulation, with little or no shock or pain following the operation.

4. **An Anaërobic Organism in Acute Rhinitis.**—Ruth Tunnicliff has isolated an organism found by anaërobic methods in all of the cases of acute rhinitis she has studied. It occurs in the early stages in the mucoid discharge, often in large numbers and generally unassociated with other germs. It gradually disappears as the discharge becomes purulent. It is also found sometimes in large numbers in the sputum and mucus of the throat of an accompanying pharyngitis, bronchitis, or tonsilitis. It was not found in thirteen normal persons and was found in small numbers in only one normal person. Carbol-gentian-violet and carbol-fuchsin are the best stains. It is Gram-negative and unstained by methylene blue, thionin, or the Giemsa stain. It can be seen by dark-field illumination. The organisms seemed generally immobile, perhaps on account of the mucus. They vary from 5 to 8 microns in length and from ⅛ to ½ a micron in width, the pointed or slightly rounded ends are usually slightly curved; sometimes a ball-shaped enlargement is seen at one end, or a ring. The organism is a strict anaërobe and grows slowly, at least at first. The author has isolated it in pure culture on alkaline goat-blood agar four times, and it grows also on the dextrose agar and ascites agar; in dextrose broth there is a flocculent growth. Some cultures have a slight odor. The organism looks like a spirochete but culturally it acts more like a bacillus, and which it is further investigations will have to show. The author is not prepared at this time to make any statement in regard to its pathogenic effects or its immunity reactions. Whether or not it is the cause of acute coryza will have to be determined by further investigation, but the author's observations showed it present constantly during the early stages in the eighteen cases examined.

6. **Sensitiveness to Resorcin.**—D. W. Montgomery states that resorcin when applied in full strength on the skin acts as a highly irritant caustic. It is a powerful antiseptic, and when applied as a strong lotion or ointment, causes an active desquamation of the upper epithelial layers. It therefore is an efficient cutaneous antiseptic, both because it kills the bacteria, and because it produces an exfoliation of the bed in which they lie. Besides being a caustic, an irritant, and an antiseptic it has an action on epithelium common to it and the tars and coal tars, so that when properly diluted it lessens cutaneous irritation, and favors the return of epithelial cells to normal physiologic function. When applied in strong dosage over large surfaces, especially if these surfaces are denuded, it may be absorbed and cause dangerous symptoms of internal poisoning, or even coma and death.

2. **Tetragenus Septicemia.**—Sir John Byers and T. Houston report the case of a boy aged 11 years who had been suffering for years from a condition that is described as a general infection or septicemia due to the *Micrococcus tetragenus,* producing symptoms in the main referable to the respiratory tract, such as catarrh, bronchitis, bronchopneumonia, throat, nasal, and ear trouble, but also producing at various times abscesses, diarrhea, and acute elevations of temperature. It was interesting to note that after the first four or five doses of an autogenous vaccine the reaction was accompanied by increased cough, slight diarrhea, and transient earache. After his temperature had become normal the boy remained very deaf, especially in one ear, and as the discharge contained large numbers of a diphtheroid bacillus it was thought wise to combine with the *Micrococcus tetragenus* vaccine small doses of a vaccine made from this diphtheroid bacillus. This appeared to have a good effect, as his deafness and the discharge from his ears quite disappeared.

4. **A New Spirocheta Found in Human Blood.**—Helen Chambers describes what she regards as a new microorganism which she has detected in normal human blood. This is collected in a small Wright's tube and is allowed to clot at 37° C. for 20 minutes. The serum which has separated is then pipetted off. If a drop of this serum is placed on a slide and covered with a cover glass ⅞ in. square and examined by dark-ground illumination, in most cases one or two organisms can be found on the slide. The remainder of the clot is returned to the incubator, and after 1½ hours the serum which has separated owing to further shrinkage of the clot is examined by dark-ground illumination. The organisms escape into the serum chiefly during the last stage of contraction of the clot, and by adopting the above procedure they are concentrated in a small volume of the serum. As a rule they are easily seen. The number found varies considerably. In the majority of specimens prepared in this way four or eight can be found on each slide; in other cases the organisms are very numerous, ten and more being found in each field of the microscope. Some of the specimens of blood containing the largest numbers have been obtained from apparently healthy people. The number of organisms found fluctuates at different times. In three cases examined six weeks ago the blood contained the organism in large numbers; on many subsequent examinations comparatively few were found. They have now, however, increased and are almost as numerous as when the blood was first examined. The organism is actively motile and is very variable both in length and thickness. The majority measure from 4μ to 30μ in length; very long forms are, however, met with. Some are extremely thin, like the *Treponema pallidum,* others are almost as thick as typhoid bacilli."

5. **Spinal Tumor with Scoliosis.**—W. Harris and A. S. Blundell Bankart report a case of psammoma of the middorsal region of the spinal cord in a woman aged 57 years. This case is interesting, first, on account of the scoliosis which is a well-recognized accompaniment of some spinal cord diseases, but which, so far as the authors can discover, has never before been described in association with a spinal tumor. The presence of spinal deformity in this case had led to a diagnosis of arthritic disease of the spine, which was supposed to be causing pressure on the cord, and when seen by the authors the patient had already been refused operation on that account. But even if spondylitis deformans ever produces compression paraplegia, this case was quite unlike an instance of that disease, for the spinal curve was a typical scoliotic curve, as stiff as such cases often are, but without any of the rigidity of spondylitis. On the other hand, the neurological course and symptoms pointed clearly to pressure of some kind upon the spinal cord, so the patient was sent into the hospital for operation. Secondly, the situation of the tumor corresponded exactly to the upper limit of demonstrable anesthesia, which is unusual. The rule is to locate the tumor in the dorsal region one or two segments higher, so as to allow for the overlapping of the sensory areas immediately above. This led to exposure of the cord above the tumor. A much more common mistake is (or used to be) to go too low. Lastly, the very slow rate of growth is worth notice. The first symptoms appeared more than seven years ago, and the legs became affected about a year after the spinal deformity was noticed. But six more years elapsed before the patient was completely disabled. This should indicate a good prognosis.

7. **Ingestion of Bacteria by the Subepithelial Lymphatic Glands.**—K. H. Digby demonstrated in healthy rabbits the constant presence of immense numbers of bacilli in the lymph structures of the appendix and Peyer's patches, and smaller numbers of cocci in the tonsils. Most of the bacteria are intracellular. Solitary bacteria and cells loaded with bacteria can also be seen in their passage through the epithelium, so that, contrary to common belief, the lymph cells are both motile and phagocytic. The universal presence of bacteria in these healthy tissues necessitates caution in examining pathological material. Bacilli found in Peyer's patches in typhoid fever are probably typhoid bacilli, but the presence of bacilli in Peyer's patches does not prove typhoid or other intestinal infection as has sometimes been assumed. Notwithstanding this difficulty a careful pathological search of the tonsils and other subepithelial lmyphatic glands might cast some light on the virus in scarlet fever and acute anterior poliomyelitis. The author advances the view that the subepithelial lymphatic glands protect the body against bacterial infection by processes of autovaccination. They also would seem to cast some light on the problem of the healthy human carrier in infectious diseases. Ledingham and Arkwright in their recent valuable publication have shown the frequent occurrence of healthy human carriers in various epidemics. In epidemic cerebrospinal meningitis the carriers may be ten times as numerous as the cases of disease. The carriers in most infectious diseases are more or less immune. Sometimes they have had a slight inflammation of the circumpharyngeal ring of the lymphoid tissue, and they usually show hyperplasia of the tonsils and adenoids. Generally the specific organism is most easily cultivated

from the tonsils of the carrier, and removal of tonsils and adenoids may occasionally be followed by its disappearance. At other times the operation is followed sooner or later by an acute attack of the disease for the first time (diphtheria, rheumatic fever, and acute anterior poliomyelitis).

June 21, 1913.

1. Spinal Anesthesia by Tropacocaine. With a Review of 1,295 Cases. J. T. J. Morrison.
2. The Lacrymal Gland in Surgical Anesthesia. L. T. Rutherford.
3. Sleeping Sickness and Big Game: A Proposed Experiment. W. Yorke.
4. Preliminary Report on an Outbreak of Febrile Disease in an Industrial School. K. M. Duncan.
5. Notes of a Case of "Nodular Leucemia." R. Reid, W. Calwell and W. W. D. Thomson.
6. A Case Illustrating Great Tenacity of Life. A. Turnbull.
7. The Influence of Marienbad Sulpbate Water on Albuminuria. M. Porges.

1. Spinal Anesthesia by Tropacocaine.—J. T. J. Morrison sums up the position of spinal anesthesia as follows: It is a procedure of proved value and simple technique. Its province is subdiaphragmatic operations. There is no prohibitive age limit. By blocking afferent paths it prevents surgical shock. It induces muscular relaxation, quiet breathing, and abdominal stillness, and thus conduces to rapidity and safety in abdominal surgery. Used with discretion in conditions of extreme asthenia and instability of the medullary centers due to toxemia, exhausting disease, traumatic shock, and old age, it is superior to ether and chloroform. It promotes the patient's comfort and nutrition in the post-operative stage. Its scope is amplified with the aid of scopolamine and morphine. By lowering blood pressure it tends to faintness and respiratory depression. The patient should therefore be carefully watched after injection, and treated as required by means of diffusible stimulants, pituitrin, saline infusion, and artificial respiration. In a small percentage of cases it is inadequate, and must be supplemented by general anesthesia. It increases the possibilities of surgery by facilitating the work of a surgeon in the absence of a competent anesthetist or assistant. The procedure should be taught in medical schools.

2. The Lacrymal Gland in Surgical Anesthesia.—L. T. Rutherford finds that in the first stage of anesthesia the internal canthi may be wet or dry, that in the second stage the lacrymal glands are always active, that in the third stage the lacrymal secretion ceases at the same time as the earliest reflexes disappear, and that this cessation usually precedes the abolition of the corneal reflex by a very short interval. The slight variability in the time of cessation of the lacrymal secretion is of no practical importance, for in no case do the glands continue to secrete *after* the abolition of the normal corneal reflex (the term "normal corneal reflex" is used here purposely to distinguish it from the "diminished corneal reflex" observed after a time in an eye which has been continuously or carelessly tested). The moment at which the lacrymal secretion is first observed, after its cessation under the influence of chloroform or ether, is of the utmost importance, and provides a reliable indication of the exact moment at which to continue the administration, if a satisfactory surgical anesthesia is to be prolonged. The time of the cessation of the lacrymal secretion during the induction period corresponds almost exactly with the time of its reappearance during the recovery period, and it is on this account that the "canthal" tear is so valuable, for it indicates when present that the corneal reflex is (or should be) obtainable, and that the amount of the anesthetic is as much as is compatible with successful anesthesia. If, then, one administers the anesthetic in quantities just calculated to abolish the lacrymal secretion and then wait, if at any time in doubt, until the secretion again appears, one may feel confident that one is well on the safe side of the border line between deep surgical anesthesia and an overdose.

3. Sleeping Sickness and Big Game.—W. Yorke states that in view of the impossibility of exterminating the tsetse fly and of the equal impossibility of removing the population from the fly belts, one must consider the only way that remains of combating sleeping sickness, namely, the advisability of attempting to destroy the reservoir of the virus. It is obvious that the mere isolation of infected human beings is futile in view of the fact that the main reservoir of the virus is the blood of the big game. Since the beginning of last year, when Kinghorn and the author announced the fact that a large proportion of the wild fauna of Africa harbored the trypanosomes of man and domestic stock, a considerable polemic has arisen over the question of the advisability of attempting to exterminate the big game in the vicinity of human habitations in fly areas. The author believes that a decisive scientific experiment should be undertaken with a view to ascertaining the effects of completely eradicating the game in a limited area. As some years must elapse before the results of such an experiment would be known, he suggests that in the meantime the restrictions relating to the killing of game by Europeans and natives should be removed in those portions of the fly areas which are in the vicinity of human habitations.

6. A Case Illustrating Great Tenacity of Life.—A. Turnbull notes that the case of the French Zouave who lived for some time after practically the whole of the head except the brain had been removed by a cannon ball is one of the classical instances of tenacity to life. Weinlechner in 1881 reported that a man had lived and been conscious for twelve hours after a fall and injuries which included fracture of the cervical spine, with laceration of the cord, paralysis (motor and sensory) of all the limbs, rupture of the sternum, bleeding into pericardial and abdominal cavities, and laceration of the spleen. Erichsen reported the case of a man who, after leaping a distance of 60 ft. down a hoist, lived for ten days, although suffering from fracture of seven ribs, perforation of the apex of the right lung, tearing of the pericardium, complete fracture of the first lumbar vertebra, and pulverization of the right os calcis. D'Arcy Power read a paper in 1890, indicating that considerable laceration can take place in the spleen and in the kidney with very slight symptoms, unless a large blood vessel is implicated. If urgent hemorrhage does not immediately follow injury, the most extreme internal injuries can often be undergone with a minimum manifestation of shock. The following case that came under the author's observation is cited to bear this statement out, and emphatically illustrates the powers of tenacity of life in the human frame: The case was that of a dock laborer aged 45 years who was admitted to the hospital nine hours after he had fallen down the hold of a ship. This man walked half a mile after receiving a fractured skull, extensive fractures of the ribs, pulping of the spleen, pulping of the kidney, and lesions in the vicinity of the solar plexus. A bowlful of blood had probably been passed by the urethra from the ruptured kidney. The patient died one hour after admission to the hospital.

Digestion of Lecithin in Diseases of the Gastroenteric Tract.—Ehrmann and Kruspe state that while the lecithins of our aliment are present in abundance in both the animal and vegetable kingdoms, notably in egg yolk, milk and butter, cereals, meat, etc., almost nothing is known of their disintegration within the body. As lecithins barely reach the colon it is evident that they are split up and absorbed in the small intestine. According to those who have

studied the subject the pancreatic enzymes split up lecithins into its components, especially glycerophosphoric acid, cholin, and fatty acids, which are then absorbed. When the pancreatic duct is ligated large amounts of unchanged lecithin appear in the feces. Hence this fact may be utilized clinically—lecithin in the feces may mean obstruction of the pancreatic duct. The authors however, have recently found that an obstructed bile duct may likewise be associated with lecithin in the feces, the degree being even greater than in obstructed pancreatic duct. Lecithin is therefore poorly utilized in obstructive jaundice. A study of the fate of lecithin in health shows that most of it passes unchanged through the gastroenteric wall. Only when diseased conditions like those narrated cause the lecithin along with the fats to lie unabsorbed in the intestine do we see the secondary splitting up of this substance or the appearance of it unchanged in the feces.

How to Determine Whether Children Are Normal.—Cimbal states that conscious inhibition of impulses, etc., occur earlier in the healthy subject in comparison with psychopaths and mild debiles, for the self-evident reason that this inhibition represents the acme of cerebral development. This want of the quality under consideration is common alike to the imbecile and to certain intellectually normal children. Intellectual tests are regarded by the author as no longer a sufficient test for a normal mind, and in any case they are scientific in character, rather than practical. The author prefers to test the imagination of the child. Apparent obstinacy is thereby found at times to be due to intellectual torpor. A purely intellectual test for imbeciles, like the memory, may show that the latter is suspiciously good. Some of the newer psychological tests for the workings of the mind—for the rapidity of impressions and degree of attentiveness—work out as well in psychopaths and debiles (and sometimes in out-and-out imbeciles), as in children of normal minds. In regard to motor tests a normal child under three years cannot control his muscular activities. After that period the normal subject begins to acquire this control, but for the psychopath years may be necessitated, and indeed a lifetime may be insufficient. Sweating and tremor on undressing, redness of the skin after slight irritation. Notably increased sensitiveness of the genitals suggest masturbation. Spasmophilia is regarded by some as indicating a psychopathic constitution. We never expect to see any coherent disease picture in these children, save in dementia precox and epilepsy. A general word like "debility" must be employed to designate the kaleidoscopic pictures which we encounter. Having decided whether a child is a "debile" the next and more difficult question to answer concerns the amount of restraint indicated. Cases must be individualized; some do best at home. Ties and bad habits may disappear under isolation.

Deutsche medizinische Wochenschrift.

June 12, 1913.

Tubercle Bacilli in the Circulating Blood.—This number of the Wochenschrift contains an entire series of articles bordering on this subject. Bacmeister asks if pulmonary phthisis be of aerogenous or hematogenous origin, and answers that to the best of his belief it occurs in both ways, and that it is simply a question of whether bacilli reach the bronchioles and peribronchial tissues from the air or the blood. The initial lesion is the same in character and rapidly proceeds to infect the rest of the system. He has reached his conclusion through animal as well as clinical investigation. The author is one of those who have studied extensively the presence of tubercle bacilli in the circulating blood. Göbel has repeated the processes used by others and shows that what was found, whatever it was, could not have been tubercle bacilli. Not only did all inoculation tests fail, but certain other tests were negative. Gobel believes that the bacillus requires far more study, for it certainly represents something unknown. Brandes and Man writing at length on the occurrence of bacilli in the blood in surgical tuberculosis, conclude that in 45 per cent. of the cases this find is positive, but that it has neither diagnostic nor prognostic significance. The presence of these bacilli in the blood of tuberculous subjects is in harmony with our theoretic requirements. All tuberculous subjects of whatever type should receive years of sanitarium treatment. Further, Casper writing on the diagnosis of bilateral tuberculous kidney, mentions his opinion that circulating bacilli may pass through a kidney without infecting it.

Aneurysm of Abdominal Aorta Ruptures Through a Gastric Ulcer.—Zypkin describes a curiosity of medicine. An aneurysm of the aorta is not itself of common incidence and this case is probably unique. It is not entirely, perhaps, a very rare coincidence, because both the aneurysm and ulcer may have had some common causal factor —syphilis for example. It might be suggested that the aneurysm by its compression wore down the wall of the stomach, but the evidence of an old gastric ulcer was very decided. At the very spot at which the aorta was to impinge on the stomach an ulcerous process had been for some time at work, and the wall was thin and non-resistent. The aneurysm therefore forced its way through the ulcer. Naturally the pressure on the gastric wall had disturbed the circulatory conditions about the ulcer. The black blood passed *per rectum* had upon his admission suggested the presence of a gastric or duodenal ulcer; while a pulsation under the hypochondrium further pointed to an abdominal aneurysm. Death occurred before a diagnosis was made. It was seen that the aneurysm, in forcing its way into the stomach had itself undergone rupture and filled the former with clots. The aneurysmal wall was itself degenerated.

Abderhalden's Reaction in Pregnancy.—Hirschfeld obtained positive results with the dialysis reaction and by means of it could determine the existence of a two weeks' gestation. In two cases he obtained a weak, positive reaction in the non-pregnant. In five cases of carcinoma the reaction was negative.—*Schweiz. Rundschau f. Medizin.*

Myasthenia Gravis.—E. Farquhar Buzzard reports the case of a girl, aged 17, who had never been ill previously. Last Easter she had "influenza," during which she had pains all over, especially in the arms. Subsequently a feeling of general bodily stiffness persisted. It was only slight and in no way incapacitated her. During the last week in September she suddenly noticed that she was very weak. She became unable to do up her hair or to raise her arms, and rising from a chair became a great effort; walking was very little affected. This condition has remained stationary since, and there have been no other symptoms whatever. She generally feels stronger toward evening. Sometimes after reading for any length of time her eyes get heavy and droop; this soon passes off if she stops reading. Her voice is always good. She has never had diplopia. The feeling of general stiffness remains. She is a well-nourished girl, and presents no abnormality apart from her muscular system. She shows considerable weakness of the trunk and neck muscles and of the muscles of the shoulder and pelvic girdles. She cannot raise her head from the bed, nor make any attempt to sit up. She is unable to raise the arm above the horizontal position, nor can she rise from a chair. She is, however, able to walk. There is no wasting of muscles, and there are no sensory or reflex changes. The electrical reactions are normal.—*Proceedings of the Royal Society of Medicine.*

Insurance Medicine.

The Habit of Smoking in Its Relation to the Insurance Examiner.—Even the insurance examiner is alive to the fact that some of the pleasurable habits, so-called innocuous, may produce effects sufficiently harmful to contribute to, if not cause, untimely deaths. Alcohol is a known factor, and now tobacco seems to be in danger of receiving its death-warrant. At the January meeting of the Life Assurance Medical Officers' Association, in London, the subject was discussed in a paper by Horace G. Turney, M.A., M.D., Oxon., F.R.C.P. The speaker regarded the subject from the standpoint of a smoker and said that when one looks back upon the array of causes of untimely death reviewed by insurance examiners, the name of tobacco as a morbific agent does not strike one as awe-inspiring, but while it may never receive a separate heading in the mortality tables, its contributing influences should be understood. In discussing the possible harmfulness of smoking, attention is given mainly to the direct toxic effects. The increased liability to cancer of the lips and tongue due to the mechanical irritation of pipe or cigar is already understood and it is taken for granted that nicotine is the active toxic ingredient in tobacco. For the purpose of discussion, Turney divides the symptoms and morbid changes produced by the prolonged use of tobacco into two headings, the nervous and circulatory. Under nervous: (a) the psychoses; (b) the family of degenerative diseases, *e.g.* tabes; (c) affections of peripheral nerves Under the psychoses, Turney says that excessive smoking is as much an effect of what is known as the neuropathic temperament as the cause of any psychical ailment, in this respect standing in the same category as other narcotic tendencies. While cigarettes have the reputation of being the most harmful of all forms of tobacco consumption, he considers that, taken singly, they are the most harmless, and he believes it is the form of smoking likely to be adopted by men who have the lowest degree of natural tolerance, and, broadly speaking, these tend to be of the neuropathic type. Again it is the form of smoking most favorable to the development of the habit as a form of tic. A man may poison himself with the nicotine, but he practises the habit more as a tic than for the sake of the narcotic effect, then puts most of his troubles down to his nefarious habit of cigarette smoking. The greater the state of nervous irritability, the more constant the habit of tic becomes, thus confirming the suspicions of nicotine poisoning. Turney therefore concludes that tobacco smoking is only a subsidiary cause of the psychoses, but grants its power of attacking nerve cells, as in the cases of tobacco amblyopia. In the family of spinal degenerations, syphilis has so monopolized the field that it is doubtful if tobacco plays any part. Tobacco may at times cause neuritis, and does aggravate neuralgia, as well as migraine, but seems to be only a contributory cause in the diseases of the nervous system. The effects produced on the circulatory system, however, are much more positive and profound. Of these, cardiac symptoms form the earliest and most prominent feature. They occur even more in the young than in the old, and the symptoms are altogether out of proportion to the physical signs and are alarming. The patient experiences a feeling of oppression, the heart seeming as if it were too big for the chest. These symptoms often come on at night and wake the patient with a start. Often the heart rate is increased, the tension low, and occasionally there is irregularity, either of the rhythmic type or due to dropped beats. Tobacco excess accounts for many cases where the examiner is disquieted by the history of palpitation, irregularity, and increased frequency of pulse in a young subject. The action of nicotine on the heart may be shown in the form of general debility. Clear signs of cardiac insufficiency after very moderate exercise, and fainting attacks may occur. Only abstinence from tobacco will clear up the diagnosis. The chief point to be considered in the effects of tobacco on the circulation is its power to produce arteriosclerosis. There is no doubt whatever that it can cause disorder of the function of the vessels, but can it set up organic disease? Of late years, through experimental work, it has been shown that nicotine is one of the substances that can set up in the arteries of rabbits and other animals changes almost identical with those of arteriosclerosis. Clinical observation in this as in other cases fills up the gap left by the laboratory. Since Erb's first description in 1898 of that highly characteristic form of vascular disease to which he gave the name of intermittirendes Hinken—or intermittent limping—every increase in our knowledge has confirmed the fact of its close dependence upon the excessive use of tobacco. The clinical aspect is more varied than was at first apparent. Besides the form which Erb described, it may appear as claudicatio intermittens, as intermittent tingling, or as pain in the feet on walking. Schlesinger, after a series of experiments, says, "In view of these observations, I should agree with Erb in giving first place to abuse of tobacco. The more cases that came under my observation, the more convincing became the significance of this as an etiological factor." The influence of nicotine upon the blood pressure is at first, in the early stage to raise it, as shown in the man who gets a sense of oppression in his chest towards the end of his cigar. This is only temporary, as it is ultimately lowered in the subject of chronic excess who has an uneasy feeling of lack of energy, without a definite cause. In the long run, the effect of tobacco excess is to raise the pressure rather than to lower it. The influence of tobacco on the digestive system may cause gastrospasm and enterospasm. Another example of the power of nicotine is to cause contraction of the unstriped muscle fiber, whether in the arterial wall or in the bowel. So far as Turney's observations and some study of the literature go, he does not consider there is much evidence that the habit of smoking can be convicted of any serious effect on the mortality tables. He says one must confess rather to a feeling of surprise that the life-long absorption of so potent a drug as nicotine by a large proportion of the male population should not be accompanied by more obvious results in the way of serious injury to the cardiac muscle than appears to be the case.

Selection of Medical Examiners.—The consensus of opinion among medical directors regarding the selection of medical examiners is that the men must be honest. H. N. Mayo says that when a man has an "M.D." attached to his name is denotes education and ability, and if he will be honest with himself he cannot otherwise than be honest with his company.—Report of the Medical Section, American Life Convention, February, 1913.

Book Reviews.

THE EVIL EYE, THANATOLOGY, AND OTHER ESSAYS. By ROSWELL PARK, M.D., LL.D. (Yale). Price $1.50. Boston: Richard G. Badger, The Gorham Press.

IT is a curious fact that one takes up a book of essays, a novel, or any other non-professional work, written by a medical man, with some feeling of apprehension, inspired perhaps by the *ne sutor* tradition, lest it may be a disappointment and lest the great physician may prove himself to be but a mediocre literary man. It is true that there are many examples in the literature of all countries which lead one not to rely too much upon this tradition, yet there are, on the other hand, numerous illustrations of the weakening of a reputation by this ambitious incursion into untried fields. In the present case there is no disappointment in store for the reader, for the work demonstrates once more that the really able man is a many-sided man, and that the fact that he can think and write acceptably on medical subjects affords a presumption that he can do the same on other subjects that interest him and to which he has devoted the needed study.

This volume contains essays on a variety of subjects, some more or less related to medicine, others dealing more with anthropology, superstition, and the history of religious thought. Among the medical essays are "A Study of Medical Words, Deeds, and Men." "The Career of the Army Surgeon," "The Evolution of the Surgeon from the Barber," "The Story of the Discovery of the Circulation," and "History of Anesthesia and the Introduction of Anesthetics in Surgery." These are all good, but they are what one might expect from a surgeon who has read and thought along lines bordering on his every day work. The more interesting are those outside of pure medicine, of which are deserving of special mention, "The Evil Eye," "Iatro-Theurgic Symbolism," and "Giordano Bruno." The second of these is one of several dealing with the religious beliefs of antiquity and the present. The author is evidently a student of comparative religion, though in some of his references, especially in his erroneous allusions to phallic worship he would seem to be rather a comparative mythologist. He is indeed somewhat inconsistent in his treatment of these subjects, sometimes implying that religion is a purification of mythological superstition and again regarding the evil practices associated with ancient religious rites as a degeneration from the celebration of deeper and purer mysteries. However, the man who ventures to write essays on religious subjects seldom pleases all of his readers, and perhaps Dr. Park will find as many who accept his phallic notions as who take a higher view of the origin of the religious instinct in man.

DIAGNOSIS UND THERAPIE DER SYPHILIDE. Part II. Therapy by San. rat. Dr. S. JESSNER. Third edition. Price 1.25 M. Würzburg: Curt Kabitzsch, 1913.

SYPHILIS of the skin and mucous membranes is briefly discussed, followed by chapters on therapeutic aids. Mercury is still called the brilliant aid; salvarsan is next taken up and lastly iodine. Local treatment is given only two pages. There seems little new in the book.

HANDBUCH DER SPEZIELLEN CHIRURGIE DES OHRES UND DER OBEREN LUFTWEGE. Herausgegeben von Dr. L. KATZ, Spezialarzt für Ohren-, Nasen-, und Halskrankheiten in Ludwigshafen a. Rh.; Dr. H. PRYSING, Prof. der Ohren-, Nasen-, Kehlkopf-, Heilkunde, Ord. Mitglied der Skad. für prakt. Medizin zu Cöln a. Rh.; und Dr. F. BLUMENFELD, Spezialarzt für Nasen-, Hals-, und Lungen-Krankheiten in Wiesbaden. III. Band, Lieferung 5, price 7 marks. IV. Band, Lieferung 5 und 6, price 8.50 marks. IV. Band, Lieferung 7, price 7 marks. IV. Band, Lieferung 8, price 4 marks. Würzburg: Verlag von Curt Kabitzsch, 1913.

WITH the appearance of the four instalments which it is now our privilege to review, this monumental work is nearing completion. In its fulness of text and in its profusion of illustration it surpasses anything that has ever been attempted in this line. The fifth instalment of the third volume continues the subject of the obital complications of disease of the nasal accessory sinuses, which is dealt with exhaustively by R. Hoffmann. In addition to the many halftone cuts and colored plates there are a number of stereoscopic photographs. This part also contains the beginning of the article on tumors of the hypophysis and its operative treatment by Prof. S. Kuttner. The fifth and ninth instalments of the fourth volume contain the continuation and completion of the article on endolaryngeal operations by F. Blumenfeld. The pathology, symptomatology, diagnosis and treatment of endolaryngeal growth are all included in this article, which, like the rest of the work is superbly illustrated. The article on tracheotomy begins in this section. The next, or seventh instalment of the fourth volume, contains the greater part of the article on tracheotomy, which is from the pen of P. Bockenheimer. A series of four colored plates show the different steps in the operation. The article on tracheobronchoscopy, by M. Mann, is begun in this section and is continued in the succeeding instalment, the eighth, which concludes Volume IV. This contains in addition the article on esophagoscopy, by H. Starck. It is difficult to put out any one part of this work for special commendation, so admirably do all the parts fulfill the needs of an ideal medical text book, with fullness of detail and accuracy and ample illustrations.

ZUR KLINIK DER EITERUNGEN DES OHRLABYRINTHS. Von Professor Dr. W. UFFENORDE in Göttingen. Mit 9 Tafeln. Price 5 marks. Würzburg: Verlag von Curt Kabitzsch, 1913.

THIS monograph deals with the clinical aspects of labyrinthine suppuration, a subject that has undergone considerable development within recent years. In detail the author discusses the pathology, symptomatology, diagnosis, treatment and prognosis, and presents in full 27 case histories. He describes his own method of operating in case of labyrinthitis, particularly in those in which endocranial complications are present. This method he regards as the safest and as the one affording the most effective exposure of the labyrinth. A series of nine excellent full-page plates are found at the end of the volume. The case histories are an aid in enabling the reader to focus concretely the facts in this interesting chapter of otology.

VERÖFFENTLICHUNG DER ROBERT KOCH-STIFTUNG ZUR BEKÄMPFUNG DER TUBERKULOSE. Herausgegeben von der Stiftung. Heft 5/7. Price, 9 M. Leipzig: Georg Thieme, 1913.

THIS book consists of two portions, the first dealing with the differentiation of the human and bovine type of the tubercle bacillus by producing experimental corneal and iris tuberculosis in the eye of the rabbit, besides experiments concerning the formation and the significance of the complement binding tuberculous antibodies, by Prof. Dr. F. Schiek, director of the Königl. Universitäts eye clinic in Königsberg i. Pr., with three colored photographs and two plates. The author concludes that it is possible to differentiate the two types of bacilli. Infection with the bovine type in the eye of the rabbit leads to rapid cheesy degeneration of it, while infection with the human type is capable of healing. The second part of the work is devoted to an article on experimental tuberculosis studies by Prof. Dr. Franz Fl. Krusius of Berlin, with 16 colored photographs and one curve. The following are some of the author's conclusions: Quantitative tuberculous vaccinations show that the incubation period of the infection quantitatives are inversely proportional; susceptibility for tuberculous infection in the different parts of the eye is, in descending order, as follows: vitreous humor, anterior chamber, cornea, conjunctiva, and lens; the radiant energy of radium, mesothorium, and the sun is not without influence upon the bacilli as well as upon the infected organism.

MECHANICAL VIBRATION, ITS PHYSIOLOGICAL APPLICATION IN THERAPEUTICS. By M. L. H. ARNOLD SNOW, M.D., author of "Mechanical Vibrations and Its Therapeutic Application"; Professor of Mechanical Vibration Therapy in the New York School of Physical Therapeutics; Associate Editor of the *Journal of Advanced Therapeutics;* late Assistant in Electro-Therapeutics and Diseases of the Nervous System in the New York Post Graduate Medical School, etc. Price $3.50. New York: Scientific Authors' Publishing Co., 1913.

DR. ARNOLD SNOW'S latest work on Mechanical Vibration with the indications and methods of employing it, takes up the subject in a thoroughly scientific manner with a consideration of all that pertains to its therapeutic uses. It will be noted by a review of the table of contents that the volume has included many recently discovered features referable to spinal stimulation in the treatment of cardiovascular, respiratory, and other affections. This work is printed in a larger volume than the author's previous work, comprising about 500 pages and 50 plates and illustrations. The work also contains many valuable tables and practical suggestions to assist the operator in the scientific employment of mechanical vibration.

Die Therapie des Ekzems. Geh. Hofrat Dr. Theodor Veiel und Dr. Fritz Veiel in Cannstatt. Price 1.20 M. Halle a. S.: Carl Marhold, 1912.

In this short concise résumé are taken up the etiology of eczema, the specificity of arsenic, predisposing and contributing factors, and the difference in the treatment of acute and chronic eczema. Special divisions are devoted to eczema of the scalp, face, external auditory meatus, mammæ, genitals, hands, feet and crural regions.

La Grossesse extrautérine précoce. By Dr. Lucien Hénault, Chief Gynecologist Hospital de St. Gilles (Brussels); Doctor of Gynecology, University of Liége; Honorary Member Belgian Society of Surgery. Brussels: Hayes, 1912.

This book is a good clear discussion based on a study of the literature and personal observations. A good classification of the different forms of ectopic with symptoms and diagnosis is given and as a diagnostic aid the opening of Douglas's sac seems worthy of consideration.

Uber die Behandlung der Hauttuberkulose. Vol. I. No. 6. Von Dr. Doutrelepont in Bonn. Price 1.20 M. Halle a. S.: Carl Marhold, 1912.

This monograph contains a fuller description of the topic treated in Vol. 100 of the *Archiv. für Dermatologic und Syphilis*. The three general forms are tumors, ulcers, and tuberculides. Of the complications elephantiasis and carcinoma are mentioned. Symptomatology and prognosis receive passing attention. The author does not claim to place before the reader all the therapeutic measures that have been employed in this condition. He mentions general treatment, tuberculin, old and new, Liebreich's cantharides, and Hebra's injection of thiosinamins; local treatment with 1 per cent. sublimate, pyrogallol salve, surgical method of total extirpation, curettage, scarification, Hollander's hot air treatment, Röntgen and Finsen rays. Tuberculosis of the mucous membrane also receives attention.

Lehrbuch der Spezifischen Diagnostik and Therapie der Tuberkulose; D. von Dr. Brandelier, Chefarzt des Sanatoriums Schwarzwaldheim in Schönberg bei Wildbad, und Dr. Roepke, Chefarzt der Eisenbahnheilstätte Stadtwald in Melsungen bei Cassel. Seventh revised edition. Price 8.30 M. Würzburg: Curt Kabitzsch, 1913.

This work has gone through seven editions in the past four years and been extensively revised and enlarged in the last one. All of the theoretical portions which were scattered throughout the work have been summarized and placed in the first chapter with a number of subdivisions (theories of tuberculin reaction; curative factors in tuberculin action). To the specific diagnosis of tuberculosis, general part, has been added a long discussion and colored plate illustrating the cutaneous tuberculin test. The special part is increased by a chapter on specific diagnosis of tuberculosis of the digestive organs. In both parts the literature on tuberculin diagnosis receives detailed and careful attention. In the chapters on specific therapy of tuberculosis, that of the pulmonary type has received a broader and more convincing consideration. In the special division on specific therapy a subdivision on tuberculosis of the digestive organs has been added. The authors are convinced that their work serves to demonstrate the efficacy of the tuberculin treatment to all.

Die Krankheiten der Mundhöle, des Rachens, und der Nase. By Dr. Grunwald in München. Third revised edition enlarged. 756 pages. Price 12 M. München: J. F. Lehman, 1912.

This detailed work is introduced by a chapter on anatomy, embryology and physiology of the parts treated and then divided into general pathology and special pathology and therapy. In the latter chapters all the measures that are advised have been personally tested by the author. A detailed account is given of the rapid procedures necessary in acute diseases of the parts. Of the larger operations which belong to the specialist and surgeon only the newer ones are discussed. Technical details are given in the form of practical hints because the author is of the opinion that they should be taught in the province of actual practise and clinical instruction. The anatomy of the nose and tonsillar region is taken up in detail and is illustrated by a series of beautifully colored plates. The embryology from ovum stage to the complete development of the inner structure of the nose is explained in a manner which permits of the explanation of all varieties of the accessory sinuses of the nose. To accomplish this it was necessary to take apart and compare 200 skulls of adults and children and those of 50 fetuses. The topographical relations of the tissues for the correct understanding of the course of phlegmons in the mouth and palate is well brought out. There is great clearness in the explanation of deformities. The bibliography is extensive, but of course not complete.

Principles and Practice of Obstetrics. By Joseph B. De Lee, A.M., M.D. Professor of Obstetrics at the Northwestern University Medical School. Large octavo of 1060 pages, with 913 illustrations, 150 of them in colors. Cloth, $8.00 net. Philadelphia and London: W. B. Saunders Company, 1913.

The multiplicity of textbooks on obstetrics leads one to credit with a great deal of courage every new author in this field. Dr. De Lee has had such an extended clinical experience in obstetrics that any book written by him and intended as a manual for students and practitioners must necessarily be favored with strict attention. Brief mention may be made of some of the special features of this work, of which the subject matter is divided into four parts dealing with the physiology, the conduct and the pathology of pregnancy, labor, and the puerperium, and a final section on operative obstetrics. This arrangement will permit an easy division of the subject to fit the usual college curriculum. The writer claims that although he has consulted other authorities, the opinions expressed are mainly the result of his own experiences in hospital and private practice. He makes diagnosis a particular feature and likewise the relations of obstetric conditions and accidents to general medicine, surgery, and the various specialties. The illustrations are largely original and based on material from the Chicago Lying-In Hospital. Their reproduction and the makeup of the entire book are worthy of special mention. Dr. Lee is firmly impressed with the idea that obstetrics as a science and art should be elevated to a higher plane and believes that the subject will be divested of most of its objectionable features in the near future, so that the field may be made more inviting to physicians and the public will be led to appreciate such special services more than in the past. As the majority of labor cases at the present time are abnormal it seems opportune to recognize the pathological dignity of the subject and when this is done we can hope for a considerable reduction of the mortality and morbidity of childbirth. The book is too extensive to permit of detailed mention of its various features and it is therefore sufficient to state that its favorable aspects are so much in the preponderance that the few faults may be passed by. The discussion of puerperal infection is very satisfactory, especially the chapter on treatment, in which the author takes a firm stand against all forms of local treatment, relying largely on general measures, including fresh air, together with special attention to diet, the bowels, and placing the patient under the best mental and physical conditions. Any specific treatment thus far advocated seems to have failed, including the use of the various sera and vaccines. Extensive surgical procedures are likewise contraindicated in the author's experience. The chapter on operative obstetrics is very satisfactory and the descriptions of the different operations sufficiently complete for all purposes. In a concluding chipter the author presents a description of his methods for sterilizing gloves, etc., and also includes reproductions of the history charts used at the Chicago Lying-In Hospital.

Über die Serodiagnose der Syphilis. Ihr Wesen, ihre Technik und ihre Practische Bedeutung. Dr. A. Bauer in Danzig, bisher Assistengarzt der kgl. dermatologischen Universitätsklinik in Kiel. Price 1.20 M. Halle a. S.: Carl Marhold, 1912.

The author explains with drawings, charts, tables, etc., the theoretical foundations necessary for the understanding of serodiagnosis. The technique of the preparation of the five components used in the production of the syphilis reaction is taken up. Three short chapters complete the booklet: 1. the specificity of the syphilis reaction; 2. the serological diagnosis of the different forms of syphilis; 3, the limits of the value of the reaction.

Über Laparo- und Thorakoskopie. Dr. H. C. Jacobæus, Privatdozent in Stockholm. With an introduction by Prof. Dr. L. Brauer. Price 6 marks. Würzburg: Curt Kabitzsch 1913.

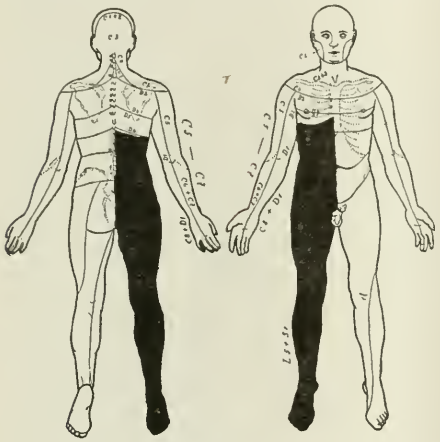
This excellent method is safely applied with no unpleasant side effects. The patients experience no inconvenience. Post mortems which have followed the examinations revealed no injury which may have been inflicted by an examination. The pleura and peritoneum usually showed a small and at times an almost invisible healed scar. In many cases the author has been able to demonstrate changes in the pleura and peritoneum which otherwise would have gone unrecognized, as primary tumors of the pleura, syphilis of the liver or tuberculous peritonitis.

Society Reports.

REPORT FROM THE TUESDAY CONFERENCES OF THE NEUROLOGICAL INSTITUTE OF NEW YORK.

First Division—Dr. Joseph Collins.

A Case of Spinal Syphilis with Disturbances of Sensibility Similar to Those Found in Syringomyelia.—Dr. C. Burns Craig said that at one time it was widely taught that multiple, disconnected, disparate symptoms were highly suggestive of syphilitic lesion of the central nervous system, indeed almost a hall mark. Larger experience with the disease, and especially more accurate aids to its diagnosis, has shown that such disconnected symptoms are not so pathognomonic as was formerly believed. When the disease is of the spinal cord and its coverings the resultant symptoms depend upon whether it is the meninges, the spinal roots, the entire substance of the cord, or definite tracts which are involved. The most common form of spinal syphilis is, of course, tabes dorsalis. We shall not discuss here the propriety of calling tabes a form of spinal syphilis, believing that the development of serology fully justifies such a classification. The next



Area of Thermal Anesthesia; Over the Same Area a Pin Prick is Not Painful.

most common form of spinal syphilis is that which produces, to a greater or less degree, at some time during the course of the disease, a transverse lesion of the cord, and which may be properly spoken of as a myelitis. A variety of this form is the spastic spinal paralysis with which the name of Erb is usually associated, although Leyden seemed to have described such cases as far back as 1874. The next most common form is the meningeal or meningoarterial, while the variety involving the roots alone is the rarest. We have recently presented from our division cases illustrative of all these varieties, and it occurs to us that a patient whose symptoms do not fit in closely with any variety (although he must be classified as amongst the second form mentioned) might be of interest.

The patient, a boiler-maker helper, thirty-four years old, had a specific infection when he was twenty-one. He took mercury and iodide of potassium under the direction of a physician for about three years. Aside from the occasional disastrous effects of drink he remained fairly well until Thanksgiving, 1911. He then fell ill, complained of a queer creepy feeling all over, a sense of numbness and of heaviness in his legs and of inability to control the sphincters. Within a week he became almost wholly paraplegic. There was never a time, however, when he could not stand if aided by a person holding him on either side. At the end of about a month, during which time he had incontinence of feces, dysuria, and incontinence of urine, he began to improve, and within three months he was able to walk about. In May, 1912, he relates that he went to Bellevue Hospital, where a Wassermann examination was made of the blood serum. It was found to be positive, and he received an intravenous injection of salvarsan. After this he made much further improvement and went to work, although his legs felt both weak and queer.

He presented himself here on March 4, 1913; his complaints than were: (1) A numb heavy feeling in the right lower extremity, with a sensation as if something were running through it. He relates that when anything is brought in contact with the leg he does not have "the right feeling." (2) A jumping sensation in both legs from the hips down which is different from the sensation just enumerated. (3) Occasional difficulty in controlling the bowels and bladder and especially difficulty in starting the urinary stream. (4) Impotency which has existed since the onset of the illness. Physical examination shows that the tendon jerks are diminished on the right lower extremity and active on the left. The abdominal and epigastric reflexes are extremely sluggish on both sides. The plantar response on the left side is extensor and on the right side is flexor. There is a thermal anesthesia of the entire right side from the sixth rib downward anteriorly, and the seventh dorsal spine posteriorly. Tactile stimuli are felt over this area, but they are interpreted as being disagreeable. When touched with the point of a pin over this area he says it feels as if he had an electric shock, which is probably to be interpreted as an increased tactile sensibility. The sensation is not that of a painful prick. There is practically no other physical sign of disease. The serum Wassermann was plus, but the cerebrospinal fluid showed no cells nor pathological reaction. This case may, therefore, be interpreted as a case of exudative syphilis, meaning thereby that the lesion was a vascular and circumvascular one, that the extent of the original lesion was comparatively limited (probably to the sixth or seventh dorsal segment, left side); that it was in the transverse direction of the cord, and that the process is tending to terminate in recovery.

Dissociation of sensibility, such as that which has been so often said to be pathognomonic of syringomyelia, but which in reality occurs in many other conditions, is a comparatively rare symptom of spinal syphilis. At least such well marked and profound dissociation as exists in this case is uncommon. In the Brown-Séquard type of paralysis, which is a well-known syphilitic lesion, we see the most common variety of sensibility-dissociation. Indeed, the present case may come within this category. But in presenting this case, it was our purpose, to direct attention to the similarity of disturbance to syringomyelia, which we may occasionally find in spinal syphilis.

Second Division—Dr. Frederick Peterson.

Subacute Combined Degeneration of the Spinal Cord Associated with Anemia.—Dr. Foster Kennedy presented the following case: Mrs. A. McI., age thirty-nine, was brought to the outpatient department of this hospital on January 22, 1913, with the history that the diagnosis of tabes dorsalis had been made upon her at another institution. Her story is briefly as follows: In November, 1912, she began to experience cramps and sensations of cold in the calves of both legs. A week later similar vague pains were experienced in the forearms and hands, and in yet another week to these morbid sensations were added tingling paresthesiæ in the toes and the terminal phalanges of the fingers, with occasional pricking sensation around the waist, which at times extended downwards

as far as the knees. In the beginning of December she began to have a difficulty in walking which she thought at first was due to general weakness, but which later was found to be due to definite ataxia of the lower extremities. Her difficulty in walking steadily progressed so that when seen in the latter third of January, 1913, she was quite unable to walk unassisted. Paresthesiæ have increased, but are most definitely felt in the hands and in the feet, and as a constricting band around the abdomen. Her complexion is said to be definitely paler than it was some weeks ago, and she appears frail and ill. Her previous health had always been good. On examination, special senses were normal, no defect was present in any of the cranial nerves. Marked general weakness of the arms and legs with considerable general emaciation. A sensory ataxia was present in the arms and legs. This was of severe degree, making it impossible for the patient to carry out any finely coordinated movements with the hands and impossible for her to walk without assistance on each side. The muscles were hypnotonic and, as before-mentioned, generally wasted. The knee jerks were absent; the ankle jerks absent; plantar reflexes were both of normal flexor type; the abdominal reflexes were, however, markedly depressed. The arm jerks were very difficult to elicit on either side. There was some diminution of pain and tactile sensation of irregular distribution in the legs. Deep muscle pain, however, was acute, but there was marked loss of sense of position in the feet and hands. Temperature sense was not affected. She had no incontinence in the sphincters, but had difficulty and slowness in initiating micturition. Heart sounds were feeble, but no valvular disease was present. Blood examination on January 25 showed hemoglobin, 67 per cent.; 4,268,000 R. B. C.; 16,000 W. B. C.; neutrophiles, 75 per cent.; eosinophiles, 1 per cent.; basophiles, 1 per cent.; large lymphocytes, 9 per cent.; small lymphocytes, 12 per cent.; transitional, 3 per cent. A certain amount of macrocytosis and polychromatophilia was demonstrable. Urine normal. Examination of the feces failed to show any precise abnormality, no evidence of intestinal parasites were obtained. The Wassermann test in the blood serum and cerebrospinal fluid was negative. The cerebrospinal fluid showed a normal globulin content, no cells, and a positive Fehling's reaction.

Some days after admission the knee jerks were obtained on each side, and for some weeks the patient improved, so that she became less ataxic and able to leave her bed for a short period each day. This improvement, however, was only temporary, and in March she began to suffer from attacks of abdominal distention which lasted a variable number of hours and were accompanied by feeling of profound nausea and occasional vomiting. The paresthesiæ in the hands, feet, and calves increased. The weakness in the arms and legs became accentuated; the arms still remained of defective muscular tone, but the legs became gradually slightly spastic. The knee jerks on March 14 were present; the ankle jerks were absent, and the plantar reflexes were both of extensor type. The loss of sense of position in the toes and in the hands was as before. The manner in which the disease has mainly progressed is in the direction of pyramidal degeneration, superimposed on a degeneration of the posterior columns. The spleen is enlarged, palpable, and tender. The hemoglobin percentage was then 56 and a mild form of poikilocytosis appeared. Number of R. B. C. 4,120,000, and of W. B. C. 4,600. Patient has been treated with cacodylate of soda and red bone marrow, massage, and forced nourishment. But progress has been downhill with the exception of the mild remission following her admission to the hospital. Owing to her being confined to bed it has not been possible to weigh her, but much flesh has been lost. Blood count on March 29 showed 44 per cent. of hemoglobin; 3,082,000 R. B. C.; 11,200 W. B. C. Poikilocytosis is marked.

Patient has been urged to allow an intravenous injection of salvarsan to be given to her as an intensive method of administering arsenic, but this permission she has refused. We have here a remarkable example of the posterolateral degeneration which occurs in association with various types of blood change. This disease was first described by Dana and Putnam, in this country, and later by Russell, Baton and Collier, in London, as subacute combined degeneration of the spinal cord. It is not necessarily associated with anemia of the pernicious type, but is frequently found as a sequela of a so-called secondary anemia of severe degree. In almost all cases the disease is progressive and the termination is fatal within three years.

THIRD DIVISION—DR. PEARCE BAILEY.

Laminectomy and Posterior Root Section.—DR. ELSBERG presented a patient upon whom he had performed a laminectomy on account of symptoms referable to the fourth lumbar posterior root on the left side.

M. C., twenty-two years of age, had been thrown out of a wagon in a runaway accident about eighteen months before. He did not feel any pain at that time. Six months later, he had began to have intermittent cramps in the left leg, and the left thigh became stiff and painful. The pain became gradually worse, and was increased upon movement. He was treated by a number of physicians for sciatica without benefit. Physical examination showed that there were a number of tender spots on the back of the left thigh, some increase of the knee and ankle jerks on the left side, slight hypesthesia over the distribution of the third and fourth left posterior spinal roots. The *x*-ray showed that there had been some injury to the fourth and fifth lumbar vertebræ. By laminectomy, the second, third and fourth spines and laminæ were removed. The spine and laminæ of the fourth lumbar vertebra were much thickened, the spinal canal markedly narrowed at this level, and the cauda markedly angulated. The dura was reddened at the spot of greatest narrowing of the canal. After removal of much bone, the left fourth posterior root was divided, and the wound then closed. Convalescence was uneventful, the wound healing by primary union, the patient was relieved of all of his symptoms. Dr. Elsberg remarked that this was the second case of this kind that he had operated upon.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held April 21, 1913.

THE PRESIDENT, DR. BROOKS H. WELLS, IN THE CHAIR.

Presentation of Instruments.—DR. MAX EINHORN presented one instrument intended to clear up the question of whether the duodenum or other parts of the intestine were affected. *X*-ray pictures of the duodenum filled with bismuth were shown. Another instrument which could be passed some distance into the intestine was shown; it had within it a wire which enabled him to show the exact position of the intestinal coils as found in the *x*-ray pictures. Just how far he could get this instrument into the intestine he could not tell. Dr. Einhorn presented another instrument for obtaining the secretions from the duodenum or other parts of the intestine without admixture of one secretion with another.

X-Ray Treatment of Uterine Fibroids, Menorrhagia and Metrorrhagia.—DR. SAMUEL STERN read this paper. He said that the Röntgen ray treatment of uterine fibroids, menorrhagia and metrorrhagia, although still more or less in the experimental stage, had already shown sufficiently satisfactory results to justify their giving it serious consideration in the treatment of these cases. Since 1905 thousands of cases had been treated and with a large percentage of very gratifying results. In the latter part

of 1911, at Dr. Brettauer and Dr. Frank's request, they began the treatment of these cases in the radiotherapy department of the Mt. Sinai Hospital, and the object of the paper was to report the results they had obtained. Altogether they had treated fifty-two cases, thirty-three of which were treated at the hospital, and nineteen in private practice. Among these were twenty-nine cases of uterine fibroids and twenty-three cases of menorrhagia and metrorrhagia. The class of cases chosen were chiefly of the more severe type, cases that had been under treatment for a number of years, most of them curetted once, or more often, without lasting relief. Several of them were suffering from various forms of heart lesions, which made radical surgical interference a practical impossibility. To illustrate the class of cases treated, and some of the results obtained, he described a few of them briefly. Their results in menorrhagia and metrorrhagia were very similar to those in the fibroid cases. In cases that did not yield to this treatment, they should keep in mind the possibility of submucous fibroids being present. Such was a case referred to by Dr. Frank, a young woman whom they had treated for a supposed menorrhagia for some months without relief. On referring her back to Dr. Frank, he discovered that she had a small submucous fibroid in the fundus; after the removal of this all her irregularities disappeared. After describing the *Modus operandi* Dr. Stern made the following summary of the present standing of radiotherapy in the treatment of uterine fibroids, menorrhagia and metrorrhagia. *X*-ray therapy was gradually assuming an important place in the treatment of uterine fibroids, menorrhagia, and metrorrhagia. It was by no means a "cure-all." A fair percentage of the cases could be cured, some benefited by the treatment, but there were cases where it would fail despite careful and energetic persistence. Improvement under treatment did not begin until the fourth or even the fifth month, and no case should be discarded as unyielding until it had been under treatment for that length of time. The percentage of curves would depend upon the proper technique of administration; it was perhaps of least value in cases of submucous fibroids, although occasionally here they also got good results. The treatment interfered in no way with any other treatment that might be subsequently resorted to in case of a failure. With proper technique there was no danger whatever of producing an *x*-ray dermatitis in these cases. There was practically no danger of producing a permanent menopause in women who were not near the climacteric period. Temporary menopause occasionally occurred in younger women, lasting in some of their cases more than eight months, and followed by a re-establishment of menstruation generally in a normal way. The sterility produced by the treatment was not permanent, and probably rarely persisted more than six months after the treatment was discontinued.

Dr. Joseph Brettauer said that he was interested in the results reported by Dr. Stern in the treatment of uterine fibroids with the *x*-ray. These results were only considered temporary, but as such were extremely satisfactory. It was now possible to make a differentiation between the constituents of the rays and to prevent the burns which were formerly so frequent, so that their application was without danger. As was the case with all new remedies, the *x*-ray would naturally be used indiscriminately by many and against this he wished to sound a serious warning. It should never be employed when the adnexa were diseased or when there was the slightest suspicion of malignancy. In women who bled irregularly about the time of climacteric a curettage, followed by microscopical examination of the scrapings, should precede any application of the *x*-ray. In the presence of submucous fibroids the *x*-ray was apparently of no avail. One such case was operated upon which showed upon microscopical examination a most interesting condition. As a rule ovaries removed with fibroid uteri showed a greatly increased number of follicles in all stages of development, while in this instance only one solitary follicle in the state of development was found. There was no decrease in the number of primordial follicles found.

Dr. Robert Tilden Frank said he thought the reader of the paper had taken a most conservative stand in contradistinction to a certain German author who reported 1,000 cases and claimed that he had not a single failure to record. Dr. Frank said he had examined microscopically but one case in which the ovaries had been treated with the *x*-rays but Dr. Robert Meyer had examined six and they had found that the follicular apparatus, especially the Graafian follicles, were destroyed. The primordial follicles were least affected. There was a certain effect upon the fibroid itself in these cases. This showed itself in the marked and peculiar hyaline and fibrous degeneration of the stroma, although the muscle cells seemed little affected. So-called *x*-ray castration in young people was rather evanescent. As to the possible effect upon future pregnancies, this remained to be determined. The *x*-ray caused cellular hyperactivity when the treatment was begun and therefore might cause increased bleeding for the first few treatments. In many cases where operation was contraindicated the *x*-ray proved a valuable addition to their armamentarium, and this applied especially to patients with severe heart, kidney, or other organic lesions. Again, in some patients who refused an operation through fear of the knife, the *x*-ray helped one out of an embarrassing dilemma. The *x*-ray often worked admirably where curettage had failed in menorrhagia and metrorrhagia. The *x*-ray was contraindicated in cases of diseased adnexa with repeated attacks of pelvic peritonitis, ovarian tumors, etc. Malignancy was quite common in connection with uterine fibroids, and therefore it was important that the gynecologist examine every case carefully and submit the scrapings to microscopical examination. This applied especially to women around the forties. The *x*-ray could never supplant operation where the fibroid caused pressure symptoms nor could it be employed when the fibroids were of rapid growth because there might be present some malignant change that called for more radical interference. The chief value of the treatment lay in its hemostatic action which in selected cases served to tide matters over for a number of years or produced complete cessation of the bleeding.

Dr. Florian Krug said that he regretted that he could not share the roseate views of those who spoke in regard to the merits of the *x*-ray cure for uterine fibroids. Many years ago he said he had stood almost alone, and called out a warning against the then prevailing enthusiasm for the much-heralded claims of the Apostoli treatment of fibroid tumors. It was then claimed that the largest fibroids would disappear under the magic melting power of the constant electric current. The busy abdominal surgeons had long records of hysterectomies that had to be performed on cases that had become aggravated by the vain attempts at fibroid electrocution. He predicted that the *x*-ray treatment of fibroids was doomed to go down in the same way that the Apostoli treatment had gone. There was a much higher percentage of malignant degeneration in fibroid tumors than had formerly been believed. Malignancy was often found in a removed specimen where no positive clinical sign existed before the operation. In many such instances the surgeon congratulated himself that he had saved the life of the patient. What was to become of these cases if valuable time was lost in dallying with *x*-ray treatment? They were told that burns were now obviated by not using strong dosage, and by prolonged treatment. Financially this was in favor of the *x*-ray specialist, who had learned to protect himself against the injuries of the Röntgen rays. Still many men had injured themselves irretrievably with this powerful but yet imperfectly understood agent. Again, how about the danger that prolonged *x*-ray treatment might of itself produce malignancy?

The Elastic Area in the Isthmus of the Uterus a Positive Early Sign of Pregnancy.—Dr. Louis Ladinski presented this paper. He stated that notwithstanding the importance in many instances of making an early diagnosis of pregnancy, there were no positive diagnostic signs of early uterine pregnancy generally accepted as reliable. The multiplicity and indefiniteness of the objective signs and subjective symptoms that were generally depended upon for the diagnosis of early pregnancy had not served to elucidate the subject. Aside from the cessation of menstruation and Hegar's sign, the other signs were only presumptive or negative. Dr. Ladinski declared that he was in accord with Winter and Ruge that the change in the consistency of the uterus was the most positive sign of pregnancy. He added the change in the consistency of the isthmus. Other signs should be given due consideration, but only in the nature of corroborative signs. In a paper read before the Section on Obstetrics and Gynecology of the New York Academy of Medicine, in February, 1907, and published in the Medical Record in April of that year, he had called attention to the elastic area at the isthmus of the uterus as a positive sign of early pregnancy. In view of the advocacy of so many indefinite and uncertain signs, it was not strange that this pathognomonic sign should have been overlooked. In early uterine pregnancy there was a circular area situated in the median line of the anterior surface of the body of the uterus, just above the junction of the body and cervix; that was to say, at the isthmus of the uterus, which varied in size according to the duration of the pregnancy. This area offered to the palpating finger the distinct sensation of elas-

tic fluctuation. It could frequently be made out as early as the fifth week, when the area was only the size of the finger tip, but it could always be felt in the sixth week when it was somewhat larger. As pregnancy advanced it increased in size in a crescentic manner and extended upward toward the fundus until the third month of pregnancy, when nearly the entire anterior body of the uterus presented a fluctuating, cystic feel to the examining finger. In eliciting this sign bimanual palpation was essential; while the uterus was fixed by counterpressure with the external hand, the anterior wall of the uterus was palpated from the tip of the cervix to the fundus. The proper interpretation of this change would invariably establish a correct diagnosis. This change could be detected by the general practitioner as readily as by the specialist. It possessed an advantage over Hegar's sign in that it could be detected as early as the fifth week, while Hegar's sign did not appear until a later period of pregnancy, not until the pregnancy was two or three months advanced. Again, it required special skill to elicit Hegar's sign. This sign of elasticity must not be confused with the softening, thinning, and compressibility of the lower uterine segment. The only conditions which showed a change in the consistency of the isthmus in addition to pregnancy were subinvolution, the result of pregnancy, and cystic tumors in the anterior wall of the uterus. In subinvolution, following delivery at term, or abortion, there was a change in the same area, but the feel was very soft and doughy, in contradistinction to the tense, elastic, and cystic feel of pregnancy. In the presence of a soft myoma or cystic fibroid in the anterior wall of the uterus, the elastic feel elicited in the uterine wall was almost identical with that of pregnancy, and this was the only condition that could not be differentiated from early pregnancy at the first examination. This was especially true when a soft myoma was associated with amenorrhea, as was frequently the case. Under these circumstances further observation and repeated examinations would be necessary in order to establish a diagnosis. In suspected ectopic gestation it was most important to decide whether or not the case was one of uterine pregnancy. Confirming the diagnosis of uterine pregnancy would at once preclude the possibility of an erroneous diagnosis of ectopic gestation, unless in a case of combined intra- and extrauterine pregnancy, and *vice versa*, with uterine pregnancy eliminated a possible ectopic gestation would be less likely to be overlooked. In tubal pregnancy, the uterus, though unenlarged, presented no change in consistency at the isthmus and hence this sign was of paramount importance in the diagnosis of tubal pregnancy. Dr. Ladinski said that in a number of his cases of extrauterine pregnancy the absence of uterine pregnancy was the principal indication for operation. In cases of early pregnancy with symptoms of threatened abortion, the area in the isthmus usually remained cystic and elastic as long as the ovum was viable. In subinvolution following abortion, a change in the consistency of a similar area was also manifest; here again the feel was distinctly soft, instead of the elastic cystic feel of pregnancy. Thus it was evident that a correct interpretation of the consistency of this area might serve to differentiate between threatened, inevitable, and incomplete abortion. This was not in accord with the generally accepted view that a diagnosis of the death of the ovum in the early months of pregnancy offered considerable doubt and could only be made after repeated examinations proved that the uterus remained stationary in size. The writer stated that he was not as yet prepared to offer an explanation as to the cause of this change in the wall of the pregnant uterus, but he expected to study the subject and report later on the results of his investigations. Dr. Ladinski said that his experience with this sign had been so extensive and so uniformly satisfactory that he did not hesitate to offer it with every confidence and assurance that it would prove equally satisfactory to all who chose to employ it.

The Municipal Disposal of Garbage; a Menace to Public Health; Shown in Moving Pictures.—Mrs. W. SPIEGELBERG read this paper and gave a lantern slide demonstration. She compared the method of collecting and disposing of garbage and refuse in American cities with that employed on the Continent and showed that the methods employed here were crude, wasteful, and unsanitary. In most European cities the method adopted was a mixed collection of ashes and garbage, which had proven to be sanitary and dustless. The refuse was removed during the day at certain hours in covered dustproof, noiseless wagons, drawn by two horses, accompanied by two men. In many of the Continental cities the street cleaning was conducted by the municipalities while in others the privilege was granted to sanitary utilization companies. In both cases the Street Cleaning Department was directly under the control of the Police Department. The scientific, economic means employed in the management of the refuse and the utilization of every particle of waste material enabled the municipalities and sanitary utilization companies to make it a profitable undertaking. If the garbage were scientifically collected and disposed of by sanitary methods, it would be worth to the city not less than $4,000,000, while under the methods now obtaining the Sanitary Utilization Company had paid but $200,000 per year for many years and in addition the people suffered from the unsanitary methods in use. In order to provide the city with a sanitary and dustless method of disposing of refuse, the following reforms were necessary, namely, a mixed collection, which required that the ashes and garbage be placed in the same receptacle, because the moisture in the garbage would completely absorb the dry ashes. This would not only do away with leaking garbage cans, but would also prevent the ash dust from being scattered when the receptacle were emptied into the carts. Whenever there was a greater quantity of ashes than garbage, the ashes should be sufficiently moistened to make the removal as dustless as steam ashes. This should be made a city ordinance or added to the sanitary code. Under the present system the ashes were scattered five times before they were finally disposed of. The men suffered very much from the fine ash dust which got into their eyes, nose, and throat. Children, men, and women in the streets were constantly exposed to this fine ash, which besides soiling their clothes, irritated the mucous membranes, causing endless trouble and suffering. There was still another advantage to be gained from mixing ashes and garbage in the same receptacle. The refuse became to a certain extent sanitary, because the lye and potash already contained in the ashes acted like a disinfectant for a reasonable length of time and preserved the garbage from decaying. Consequently being almost odorless, the garbage would not attract flies and thus the pollution of water, milk, and food would be prevented. The ashes also acted as a cleanser for the receptacles. In winter they would prevent the garbage from freezing into solid masses which required much time and labor to dislodge. There was a sanitary code requiring garbage cans to be covered and this should be enforced and if necessary with the cooperation of the Health Department and the Police Department. The dustless and sanitary collection in the way described would necessitate but two removals, instead of three as at present, and thus the work would be simplified and the cost of collection lessened. By a scientific and economic management of the waste materials the Department of Street Cleaning of any city could be put on a self-maintaining basis. This nation was more wasteful than any European country and for that reason the revenues would be greater here from the waste materials. Millions were spent yearly in combatting tuberculosis and other contagious diseases, but they could never be stamped out until the tenements were thoroughly cleaned up by providing a sanitary, dustless collection and disposal of garbage. Likewise incineration for large cities had proven to be the most sanitary and profitable, and with a perfected system of covered motor trucks, the stables, dumps, scows, and manure heaps would be eliminated and this would prove a permanent means of eradicating flies, all kinds of bugs, and small vermin. This incineration method would include the disposal of dead animals and would eliminate unsanitary conditions besides yielding the municipality a large revenue. It was estimated by conservative sanitary engineers that in the City of New York, if the 3,000,000 and more tons of garbage collected every year were converted into electrical energy, the electricity generated would be worth at a minimum at least $3,000,000 a year and would furnish power to run the subways, elevated, and surface lines of the city. In addition to this the slag would yield to the city a profit of $250,000. In order to have a really clean city the following sanitary regulations should be enforced before the advent of the fly season: 1. All wagons now uncovered bearing Health Department permits, such as those for steam ashes, manure, sand, lime, and mortar from demolished buildings, sewer refuse, etc., should be covered; the private ash and garbage wagons having numerous bags and barrels dangling in the rear should not be tolerated. Such a sight would not be permitted in a Western town. 2. The men who collected offal from the butchers should not be allowed to sit on the curb to assort it; they and the soapfat men should be obliged to have covered receptacles within their wagons. 3. Another great menace to health were the uncovered street sweepers' cans filled with manure. They afforded another feeding and breeding place for flies and mosquitoes, especially near the fruit peddlers; these receptacles whether full or empty should be kept in an iron covered box on the curb or sidewalk. German cities had already adopted this innovation. 4. The Tenement House Commission and the Building Department

should make a thorough investigation and have a properly appointed and ventilated place provided in every flat house for the waste paper, ash, and garbage receptacles. It would be found that a great number of tenements, both old and new, were without this most needed sanitary precaution, and therefore the barrels were either on the sidewalks or in the basement halls or in the cellars. The Tenement House Commission should make it obligatory that the garbage receptacles were emptied twice in twenty-four hours. This would greatly relieve the unsanitary conditions in old and dark three to five room tenement house apartments. 5. Persons caught in the act of littering the streets and public places with paper, and householders or storekeepers allowing them to accumulate on the sidewalks, should be fined. 6. The filthy, disease-breeding old leather car straps should be replaced by sanitary glazed iron ones, in use in some of the subway cars. 7. The equally dirty, disease breeding old carpet seats in most of the surface cars, should be removed and replaced by bamboo or perforated wood. 8. Health officers should be detailed regularly to inspect the exceedingly unsanitary conditions caused by dirt and expectoration in the subway and elevated railroad platforms and stairways, but in particular the dreadful condition at the Brooklyn Bridge. 9. At least three times yearly all large water tanks on public or private buildings should be inspected and the owners compelled to cleanse them thoroughly to avoid typhoid and many other diseases. These sanitary lessons would teach the masses of the people a much-needed object lesson in cleanliness and orderliness and arouse civic pride to assist the Department of Street Cleaning, the Health Board, and the Police Department in keeping the streets, sidewalks, parks, and public buildings as clean as was the case in all European cities. There was no reason why an American city should continue to tolerate the antiquated, insanitary methods with which all were familiar. There was no reason why every city in this country should not be just as dustless, odorless, flyless, and wholesome as Fuerth or Berlin.

The Physiological Treatment of Flat Foot.—Dr. Jacob Teschner read this paper (see page 63).

Pathological Society of Philadelphia.

At a stated meeting held May 22 Drs. K. M. Lynch and J. N. Henry presented specimens of "Metastatic Melanotic Sarcomatosis." The organs came from a man who had lost an eye, according to his statement, as a result of traumatism, and who presented nodular enlargement of the liver and brownish discoloration of exposed parts of the body. After death melanotic sarcoma was found in the back of the orbit whence, it was discovered on further inquiry, the eye had been removed by a surgeon some time previously, and secondary deposits were present in almost every organ of the body including the adrenals.

Dr. E. Burvill-Holmes presented a specimen of "Blood from the Peripheral Circulation of a Case of Puerperal Septicemia." The woman had been delivered of twins and presented a classical picture of puerperal septicemia. The number of leukocytes varied from about 43,000 on the 6th day to 13,000 along about the 15th day. When a stained smear of the blood was examined, with a view of excluding the existence of malarial fever, a leukocyte was found containing a string of six cocci and the remains of others.

Dr. George B. Wood demonstrated sections of "A Chronic Inflammatory Tumor of the Nasolacrymal Duct showing Cyst and Giant-cell Formation." The tissue came from a woman on whom forcible dilatation of the nasolacrymal duct had been practised, with the subsequent development of a chronic swelling at the site of manipulation. The tumefaction varied in size from time to time, apparently increasing at times when inflation of the nares was practised. Fearing that the growth might be malignant it was removed surgically, and histologic study showed that it contained numerous large and small cyst-like cavities, as well as foreign-body giant-cells.

Dr. Michael Wohl presented a paper entitled "Myiasis with Report of a Case." He pointed out that deposition of fly-larvæ in wounds or openings on the surface of the body is not at all uncommon, infestation with certain varieties being naturally less common than with others. The ordinary house-fly is the usual offender. The eye, the ear, the nose, and the digestive tract suffer the most frequently, and the symptoms vary accordingly. The case reported was characterized by abdominal pain and diarrhea. On developing the larvæ found in the stools, the flash-fly was known to be the cause.

Dr. Alexander Randall presented a communication entitled "The Pathology of Benign Polyps of the Male Urethra," with lantern demonstration. He discussed the various forms of neoplasm involving the male urethra, illustrating the several types by appropriate photographic reproductions on the screen.

Dr. G. E. Pfahler presented a communication entitled "The Healing Process of Osteosarcoma under the Influence of the *X*-rays; Report of Ten Cases"; with lantern-slide demonstration and exhibition of patients. He showed how under the influence of *x*-ray applications destruction of the cells of osteosarcomata took place, with replacement of line salts and ossification, continuing even for a long time after *x*-ray applications have been discontinued. The tumors are not entirely removed, although at times considerably reduced in size, but they no longer exhibit activity, and the patients continue to live for periods up to twelve years and more.

Drs. John A. Kolmer, Whitridge Williams, and Ernest Laubaugh presented a communication entitled: "Complement fixation in Syphilis with Spirochete Antigens."

Drs. John A. Kolmer and Arthur J. Casselman presented a communication entitled "Concerning the Wassermann Reaction with Normal Rabbit Serum."

Drs. R. C. Rosenberger and U. Scanlon read a paper entitled "The Occurrence of Bacillus Aerogenes Capsulatus in Various Organs." They made a study of liver, spleen and kidneys from the bodies of a number of patients dead of different diseases, and succeeded in finding the encapsulated gas generating bacillus in a moderate proportion of cases; sometimes with and at other times without definite gas-production.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Medical Examining Board of Virginia.

June, 1912.

(*Concluded from Vol.* 83, *p.* 1152.)

OBSTETRICS AND PEDIATRICS.

1. Diagnosis of pregnancy at third month.
2. Diagnosis of extrauterine pregnancy.
3. (a) Dangers of the use of chloroform during pregnancy and labor. (b) Indications for use of an anesthetic during labor.
4. What constitutes morbidity during the puerperium and mention most important means of preventing same.
5. Management of the third stage of labor.
6. Mention the indications for the induction of labor.
7. Management of a case of pharyngeal diphtheria.
8. Causes and diagnosis of a case of empyema.
9. Differentiate between subacute cervical adenitis, tuberculous adenitis of bovine type, and tuberculous adenitis of human type.
10. Give the number of calories and the percentage of fat, sugar, proteid, and lime water in the following milk mixture:

Milk, 4 per cent.	15	ounces
Sugar of milk	1⅛	"
Lime water	1½	"
Plain water	13½	"
	30	"

SURGERY AND GYNECOLOGY.

1. Describe operation for removal of the glands of the neck; what vessels and nerves would likely be injured, and how avoided?
2. Give diagnosis and treatment of synovitis of knee-joint (non-tubercular).
3. Diagnosis and treatment of fracture of neck of the femur.
4. Give the operation for radical cure of umbilical hernia; name tissues that are brought together.
5. Differential diagnosis between congenital and acquired talipes.
6. Etiology and treatment of osteomyelitis; what part of the bone does it usually attack?
7. Give diagnosis between hematocele and hydrocele of tunica vaginalis, with treatment of each.
8. Etiology, diagnosis, and treatment of pyelonephritis.
9. What relative position to each other do the ends of the bone occupy in a Colles fracture? Give method of reductional treatment.
10. Diagnosis and treatment of acute anterior; acute posterior urethritis.
11. Describe in detail operation for complete rupture of perineum.

12. Give treatment of retroversio uteri.

HYGIENE AND PREVENTIVE MEDICINE.

1. What is the safest disposal of public sewage? Describe the process.

2. Briefly outline the precautions to be taken in a community where typhoid fever has developed.

3. (a) For the purification of large quantities of water, such as is needed for large cities, what is the most available, satisfactory, and efficient method? (b) Construct a rough outline of the general arrangement of a filter plant.

4. (a) What is the difference in antitoxins and bacterial vaccines? (b) Give example of each. (c) How should they be used?

5. Give prophylaxis of hook worm disease.

MEDICAL JURISPRUDENCE.

1. Give proper manner of making post-mortem examinations.

2. What would be the appearance of a body that had been drowned, and not to have been in the water more than two or three hours?

3. What constitutes a "Live Birth?"

4. What is the appearance of an infant born alive at full term?

5. What do civil and criminal responsibility imply?

ANSWERS.

OBSTETRICS AND PEDIATRICS.

1. *Pregnancy at the third month* should show: Absence of menstruation, changes in the mammary glands, morning vomiting, purplish hue of the vagina, the os is soft and is low in the vagina, and the abdomen is flat.

2. "When extrauterine pregnancy exists there are: (1) The general and reflex symptoms of pregnancy; they have often come on after an uncertain period of sterility; nausea and vomiting appear aggravated. (2) Then comes a disordered menstruation, especially metrorrhagia, accompanied with gushes of blood, and with pelvic pain coincident with the above symptoms of pregnancy; pains are often very severe, with marked tenderness within the pelvis; such symptoms are highly suggestive. (3) There is the presence of a pelvic tumor characterized as a tense cyst, sensitive to the touch, actively pulsating; this tumor has a steady and progressive growth. In the first two months it has the size of a pigeon's egg; in the third month it has the size of a hen's egg; in the fourth month it has the size of two fists. (4) The os uteri is patulous; the uterus is displaced, but is slightly enlarged and empty. (5) Symptoms No. 2 may be absent until the end of the third month, when suddenly they become severe, with spasmodic pains, followed by the general symptoms of collapse. (6) Expulsion of the decidua, in part or whole. Nos. 1 and 2 are *presumptive signs;* Nos. 3 and 4 are *probable signs;* Nos. 5 and 6 are *positive signs.*" (*American Textbook of Obstetrics.*)

3. ANESTHETICS are used in labor to lessen suffering produced by labor pains; to lessen the pain attending obstetric operations; to relax the uterus when its rigid contraction interferes with version; to promote dilatation of the os uteri; to reduce excessive nervous excitement which may interfere with progress of early stage of labor; to relieve eclamptic convulsions and mania; in cases of uterine inversion to relax the constricting cervix and so facilitate replacement; in bipolar version to lessen pain of introducing the hand into vagina; in precipitate labor to suspend action of voluntary muscles and retard delivery; in all cutting operations upon the abdomen; and sometimes in sewing up a lacerated perineum when many sutures are required. (From King's *Obstetrics.*)

Dangers: It lessens the efficiency of the uterine contractions; it predisposes to postpartum hemorrhage; and, if given too freely, may be followed by headache, nausea, and vomiting.

4. Morbidity during the puerperium is anything in addition to the normal accompaniments of an average or normal labor. Prolonged labor, shock, hemorrhages, malpresentation, or malposition, the use of instruments, abnormalities of the fetus, and sepsis are the main factors. The patient should be put in the best possible condition before labor, all abnormalities should be corrected where possible, and examinations should only be made when necessary and always with aseptic precautions.

5. During the third stage of labor, one dram of fluid-extract of ergot is administered and irritation of the uterus by friction through the abdominal wall is practised for ten or fifteen minutes. If the placenta is not expelled by this time, the uterus is firmly grasped between the thumb and four fingers and compressed. Firm pressure is then made from above downward and backward in the direction of the pelvic canal. This usually causes delivery of the placenta. A vulvar pad of salicylated cotton and carbolized gauze and an abdominal pad and binder are then applied. (*Pocket Cyclopedia.*)

6. Conditions that justify the induction of premature labor: (1) Certain pelvic deformities; (2) placenta prævia; (3) pernicious anemia; (4) toxemia of pregnancy; (5) habitual death of a fetus toward the end of pregnancy; (6) hydatidiform mole; (7) habitually large fetal head.

7. In *pharyngeal diphtheria,* the patient should be isolated and put to bed, and kept on a milk diet. The room should be well ventilated, the air kept warm and moist; mild antiseptic solutions may be used for nose and throat; the bowels should be kept open with small doses of calomel; diphtheria antitoxin should be administered as early as possible, and in a sufficiently large dose; tonics and stimulants should be given as required. The rest of the family must be kept away from the patient, and all infected articles should be soaked in a solution of corrosive sublimate or carbolic acid.

8. *Empyema* is generally secondary to pneumonia, tuberculosis, scarlet fever, or other exanthem, suppurative inflammations, or traumatism. The pneumococcus, streptococcus, and staphylococcus are the bacteria most frequently found. The condition is diagnosed by finding the symptoms of fluid in the pleural cavity; this is withdrawn by a needle and on examination is found to be pus; a leucocytosis is also present.

9. In *subacute cervical adenitis,* the patients are generally under three years of age, there is no suppuration or caseation, the glands do not adhere to skin or deeper tissues, and the condition responds to constitutional treatment.

In the *tuberculous adenitis,* the patients are generally from three to ten years of age, caseation and suppuration generally occur, and the tubercle bacilli can be found in the pus.

To differentiate between tuberculosis of bovine type and that of human type is difficult. "There are certain slight but constant differences between the bacilli isolated from human tissue lesions and those of bovine origin. The bacilli obtained from cattle are shorter, straighter, and thicker than those obtained from man; they are cultivated less readily, as a rule, on artificial media, and they are uniformly much more virulent for rabbits. In glycerin broth 2 per cent. acid to phenolphthalein, and containing at least 3 per cent. of glycerin, the reaction produced by human cultures remains permanently acid to phenolphthalein, while with bovine cultures the originally acid reaction diminishes and when the conditions for the multiplication of the bacilli are favorable a feebly alkaline reaction is eventually reached." (Jordan's *Bacteriology.*)

10. Milk, 4 per cent. contains .04 ounces of fat, .04 ounces of sugar, and .04 ounces of proteids.

As the 15 ounces of milk is diluted to 30 ounces, these quantities will be .02 ounces.

Sugar, 2 per cent. of 30 ounces..... = 0.6 ounces
Add 1⅛ ounces (in the mixture) = 1.125 ounces

Total....1.725 ounces of sugar, which is 5¾ per cent. of 30 ounces.

Lime water, 1½ ounces = 5 per cent. of 30 ounces.

PERCENTAGES are, therefore: Fat..... 2 per cent.
Sugar of milk 5¾ "
Proteids..... 2 "
Lime water... 5 "

In 30 ounces: Fat 2 per cent. = 0.6 ounces = 18 grams
Sugar 5¾ " = 1.725 " = 51.75"
Proteids 2 " = 0.6 " = 18 "

The calorie coefficients (of Atwater) are:
Fats, 8.9; Sugar, 4; and Proteids, 4.

Hence Fat = 18 × 8.9 cal. = 160.2 calories
Sugar = 51.75 × 4 " = 207.0 "
Proteid = 18 × 4 " = 72.0 "

Total..... = 439.2 calories.

SURGERY AND GYNECOLOGY

1. "The *excision of tuberculous glands* is often an extensive and difficult operation because of the number and deep situation of the glands to be removed, and of the adhesions to surrounding structures. The skin incision must be sufficiently extensive to give access to the whole of the affected area, and to avoid disfigurement should, whenever possible, be made in the line of the natural creases of the skin. When glands are to be removed from both anterior and posterior triangles, the best access is obtained

by a Z-shaped incision, the upper limb running parallel with the lower jaw, the vertical limb along the sterno-mastoid, and the lower limb parallel with the clavicle. In exposing the glands the common facial and other venous trunks may require to be clamped and tied. Care must be taken not to injure the important nerves, particularly the spinal accessory, the vagus, and the phrenic. The infra-maxillary branches of the facial, hypoglossal and its descending branches, and the motor branches of the deep cervical plexus are liable to be injured, and should, if possible, be conserved. The dissection is rendered easier and is attended with less risk of injury to the nerves if, instead of a knife, the conical scissors of Mayo are employed. In the removal of matted glands beneath the sterno-mastoid, it may be necessary to cut this muscle across and to reflect the divided ends upwards and downwards; if the muscle itself is infiltrated with tubercle, the affected portion is removed along with the glands. When the glandular mass is closely adherent to the internal jugular vein, the operation is rendered easier by ligating the vein at the root of the neck and removing it from below upwards along with the glands (Watson-Cheyne). When the glands are extensively affected on both sides of the neck, it may be advisable to allow an interval to elapse rather than to operate on both sides at one sitting. In closing the wound, the platysma and cervical fascia should be reunited by means of a fine catgut suture and the skin edges brought together by Michel's clips; if drainage is called for, a very fine glass tube should be introduced through the skin and fascia at a little distance from the main wound." (Thomson and Miles' *Surgery.*)

2. *In non-tubercular synovitis of the knee-joint,* the knee is held in a semiflexed position, the joint is hot and painful, there is a swelling on each side of the patella and also above that bone, fluctuation may be obtained. Treatment consists in immobilization of the joint, bandaging, application of lead and laudanum lotion, ice is of use in the very early stages, later on (if pain is present) hot applications are of service; if the tension is very great leeches or aspiration may be of benefit. Later on, massage and passive movements are serviceable.

3. *Extracapsular fracture of neck of femur.* There are: History of injury; pain, bruising, and swelling; crepitus (in unimpacted fractures); loss of power of walking (as a rule); eversion; shortening of the limb; the great trochanter is raised, everted, and is nearer to the mid line. *Treatment*: Unless there is great deformity, it is not advisable to break up impaction. Bony union always occurs. The patient should be anæsthetized, and traction kept upon the leg during fixation. A stirrup extension is first put on, and then the leg is firmly bandaged to a long Liston splint, with the eversion corrected. The chest is fixed to the splint by a binder; the foot of the bed is raised, and a weight of 8 or 10 pounds is put on to the cord of the stirrup extension. Hodgen's splint may also be used. Union occurs in six weeks. (From *Aids to Surgery.*)

4. *Operation for radical cure of umbilical hernia.* "(1) Incise at first through skin and fascia only: the incision is elliptical, with upper and lower ends in the median line, and widest part opposite the greatest width of the hernia. (2) Carefully deepen the wound on one side until the abdominal aponeurosis (sheath of the recti) is reached, aiming to come down upon it a short distance to the outer side of the hernial neck. (3) Having once reached the rectal aponeurosis, similarly expose this aponeurosis and the neck of the hernial sac all around the outline of the ellipse. All bleeding is controlled by clamp and ligature. (4) The hernial sac is now incised and its contents dealt with as indicated. Adhesions are separated. Excess of omentum is ligated and excised. All remaining contents of the sac are returned to the abdomen—and kept in place by a large, anchored gauze pad—which is removed just before closure of the abdomen. (5) The entire sac, with the umbilicus and the coverings included in the ellipse, is now excised—dividing the peritoneum in an elliptical manner about the neck of the sac. (6) The peritoneum—or the peritoneum and transversalis fascia together—is sutured with interrupted or continuous gut sutures. (7) The borders of the abdominal ring—formed by the sheaths and margins of the recti muscles—are freshened with curved scissors. The edges of the ring are then brought together with interrupted sutures of kangaroo tendon or chromic gut—using either the plain interrupted suture, or the mattress type. (8) The skin and fascia (unless the fascia be thick enough to require separate gut suturing) are sutured with interrupted silkworm-gut sutures. (9) The part is then well supported by an abdominal dressing." (Bickham's *Operative Surgery.*)

5. Points of distinction between Congenital and Acquired Talipes Equino-varus:

	CONGENITAL.	PARALYTIC.
History:	Affection has existed from birth.	Not developed till second or third year.
Feet affected:	Bilateral.	Generally unilateral.
Circulation:	Good.	Limb cold and blue.
Muscles:	Little wasting.	Marked wasting.
Electrical reactions:	Not much impaired	Absent in paralyzed muscles.
Growth of bones	Unimpaired	Impaired.

(*Aids to Surgery.*)

6. Acute infective osteomyelitis. *Causes*: "The general vitality is lowered, and there is some focus of ulceration in the mouth or throat, by which organisms enter and circulate in the blood. All that is now necessary is that some part of a bone should have its vitality depressed by a blow, strain, or exposure to cold, and the organisms then attack it. The bacteria most commonly found are the staphylococci, but streptococci are present occasionally. The disease usually begins in the new growing bone at the end of the diaphysis, rarely in the epiphysis. The lower ends of the femur and radius, the upper ends of the tibia and humerus, are the commonest seats.

"*Treatment* must be very prompt. A free incision must be made through the periosteum and the pus evacuated. In any case, whether pus is found or not, the surface of bone must be gouged away to expose the medulla freely, and any gangrenous tissue scraped out. The cavity must then be washed out and freely drained. The wound in the soft structures is not closed in any part. If symptoms of pyemia occur, it may be necessary to amputate the limb through the joint or bone above, so as to cut off the source of emboli. When a large portion of, or the whole diaphysis is necrosed, there are two courses: either to cut short the disease by removing the dead portion at once, or to leave the sequestrum to stimulate the formation of an involucrum. Where there is a single bone, as in the arm and thigh, the sequestrum is left; where there is a double set of bones, as in the forearm and leg, the sequestrum is removed at once. Celluloid, zinc, and ivory rods have been inserted to stimulate osteogenesis. In most cases it is doubtful how much bone is actually dead, so that it is better to open up the cloacæ in the newly-formed involucrum to remove the sequestrum. The cavity heals by granulation." (*Aids to Surgery.*)

7. In *hematocele*: The tumor is solid, opaque, tense or doughy, globular in outline, the onset is generally sudden with history of an injury; the scrotum may be ecchymosed.

In *hydrocele*: The tumor is elastic or fluctuating, translucent, pyriform in shape, and is chronic.

Treatment of hematocele: Rest in bed, with the parts elevated; application of evaporating lotions; if there is much effusion, paracentesis may be indicated. Radical treatment includes excision of the sac, with turning out of the clot; sometimes castration is necessary, particularly in old people, or where the pain is very severe.

Treatment of hydrocele: Tap the cavity, and remove the fluid; radical treatment includes injecting the cavity (after tapping) with tincture of iodine, or excision (partial or complete) of the tunica vaginalis.

8. *Pyelonephritis* "is usually due to extension of sepsis from the bladder in cases of stricture, enlarged prostate, and spinal injuries. It may be due to calculus in the kidney or ureter, or stricture of the ureter. Organisms spread upwards along the mucous membrane or lymphatics of the ureter or along strings of mucus, and cause pyletitis. The bacteria further invade the lymphatics around the renal tubules and give rise to abscesses. Acute inflammation causes death from uremia, but if the process is chronic pyonephrosis is the result. In acute cases a rigor follows an operation on the urinary passages, associated with fever and vomiting. The patient gets into a typhoid condition, and dies in two or three weeks from uremia. In chronic cases the onset is insidious. There is some pain in the loin and an irregular intermittent temperature. The urine is alkaline and contains pus and casts. The case terminates in death from toxemia. *Treatment.*—The cause must be attended to and the bladder regularly washed out, while a large quantity of fluids should be drunk. Hot fomentations and cuppings over the loins relieve the pain, and urotropin is the best internal antiseptic." (*Aids to Surgery.*)

9. *In Colles' fracture,* the lower fragment forms a prominence on the dorsal aspect; above the lower fragment is a well defined hollow. On the palmar aspect, just above

wrist is a projection formed by the end of the upper fragment. Reduction is effected by extension with the hand supinated and adducted, combined with manipulation of the fragments.

10. *The symptoms of acute anterior urethritis* are: An incubation period of 24 hours, a tickling or an itching sensation of the meatus, which is red, glazed, and often colored with grayish, opaline mucus; the discharge is scanty at first, but gradually increases. At the end of 3 or 4 days the redness and congestion about the meatus increase and may cause edema, phimosis, and paraphimosis. Lymphangitis is present. The discharge becomes thick and purulent. Ardor urinæ, chordee, and frequent urination are now present. At this stage, when the urine is passed into two glasses, in the first glass the urine will be cloudy; in the second, clear. The symptoms just mentioned usually last for about 4 weeks, when they gradually abate.

Symptoms of Acute Posterior Urethritis.—The discharge decreases; the frequency of urination increases; vesical tenesmus may be present; there is considerable pain; hematuria, albuminuria, and retention of urine are also symptoms. When the urine is passed into two glasses, both specimens will be cloudy.

Treatment of acute anterior urethritis consists in rest, light diet, cleanliness, laxatives, irrigation with hot solution or permanganate of potassium (1:2,000); a one per cent. solution of protargol is also used; internally, urinary antiseptics, such as salol or methylene blue, are used. In *acute posterior urethritis,* in addition to the general treatment mentioned above, opium in suppository may be given; copaiba or salol may be administered; irrigations are discontinued; complications may require treatment.

11. *Operation for lacerated perineum*: "The labia are seized with Allis' forceps at the level of the lowest caruncular mytiformes. A guide stitch is placed in the posterior vaginal wall directly under the external urinary meatus. By pulling one Allis forceps and the guide stitch in opposite directions outward and downward, the posterior sulcus is exposed; denudation is required, even in a recent tear, for a part of it is always submucous. The other sulcus is exposed and denuded. Then by holding the guide stitch upward in the middle line and pulling the forceps apart the mucous membrane between the sulci is denuded or freshly torn surfaces covered with granulation-tissue are scraped with the edge of a knife. The ruptured levator ani muscle in the posterior sulci is united with a double tier suture of chromic gut, two half-hitches being taken in the stitch as it turns upward after coming down from the apex of the wound, in its deeper portion to the base. One knot at the apex of the sulcal denudation secures the stitch. The retracted ends of the transversus perinei and bulbocarvernosus muscles are brought together by silkworm sutures. Finally, a single stitch at the top of the perineal wound unites the posterior commissure of the vulva, restoring the fossa navicularis. The perineal stitches are knotted; they are removed on the twelfth day." (Hirst's *Obstetrics.*)

12. *Treatment of retroversio uteri:* Remove the cause, if possible; replace the uterus and keep it in position by pessaries, tampons, and knee-chest position; pelvic massage and vaginal douches; proper hygiene, particular attention being paid to the bowels, clothing, and exercise. *Curative treatment*: The choice lies between ventral suspension of the uterus and shortening of the round ligament.

HYGIENE AND PREVENTIVE MEDICINE

1. The biological (or bacterial) process of sewage disposal is probably the best and safest.

"The actual changes which take place in sewage, as the result of bacterial action, are somewhat complex and obscure, but they have been aptly described by Rideal as consisting mainly of three stages. In the first stage, or that of anaërobic liquefaction and preparation by hydrolysis, the albuminous matters, cellulose, and fats are broken up into soluble nitrogenous compounds, fatty acids, phenol derivatives, gases, and ammonia. In the second stage, or that of semi-anaërobic disintegration of the intermediate dissolved bodies, a further formation of ammonia, nitrites and gases takes place. In the third stage, or that of aeration and nitrification, ammonia and carbon residues are changed into water, carbon dioxide, and nitrates."

A septic tank is a specially constructed tank for the treatment of sewage; in it the sewage as such is destroyed, and new substances are built up in its place. In *Cameron's septic tank* system "the sewage is first led into a tank from which air and light are excluded. Digestive changes take place in the sewage within this tank as the result of anaërobic bacterial action, which is favored by the darkness, the absence of air, and the perfect stillness at which the sewage is maintained. Under these circumstances much of the solid matter is rendered soluble and dissolved." (Notter and Firth's *Hygiene.*)

2. The entrance of typhoid fever into the human organism may be prevented by boiling all water that is to be used for drinking or for washing dishes, etc.; milk should be boiled also; and no ice should be put *in* water or other drink or food; flies should be kept out of the house as far as possible, by means of screens or otherwise; all discharges from the sick person must be disinfected; all utensils, dishes, etc., used by the patient must be thoroughly cleansed, and boiled every day; soiled linen must be soaked in a disinfectant solution before being washed; after each attendance on a patient, physicians, nurses, and others should wash their hands in a disinfectant; thorough sterilization of all bedding, etc., must be performed after the disease is over.

3. Filtration is an efficient method of water purification. Ordinary filter beds for the purification of water are tanks of varying size, shape, and construction; the walls may be vertical or sloping; upon the paved bottom are pipes to carry off the filtered water. Above these pipes are successive layers of coarse gravel, fine gravel, coarse sand, and at the top fine sand about four feet deep. Through these layers the water passes. *Dibdin's bacteria beds* are based on "the idea that purification in a filter bed is not brought about wholly at the surface, but that the whole bulk of the filter is concerned therein, and experiments were made to determine the results of filling a bed and restraining the outflow for different periods, thus giving the organisms throughout the bed the same opportunity for action." (Harrington's *Hygiene.*)

4. See PATHOLOGY AND BACTERIOLOGY, 9.

5. *Prophylaxis of hoak-worm disease*: Children and adults should be made to wear shoes; proper toilet facilities should be provided, and their use enforced; bathing or wading in shallow water should be forbidden; a proper water supply should be available for drinking purposes; and prompt recognition and treatment of all cases should be encouraged.

MEDICAL JURISPRUDENCE

1. Reference must be made to a large textbook on Pathology or Medical Jurisprudence; the answer is too long for insertion here.

2. "Supposing the immersion not to have been over two or three hours, and the inspection to be made immediately, the face will be found to be pale, the expression placid, the eyes half open, the eyelids livid, and the pupils dilated, the mouth half closed or open, the tongue swollen and congested, often indented by the teeth, and perhaps lacerated; the lips and nostrils covered with a mucous froth, which issues from them. The skin is cold and pale, and generally contracted so as to present the appearance called 'gooseskin.' This, being a vital act, is a pretty sure sign that the body was living when immersed in the water. It is not dependent on cold, as was at one time supposed. Cadaveric rigidity usually comes on early in the drowned, hence the body is often found with the limbs stiffened. (Reese's *Medical Jurisprudence.*)

3. To constitute a "live birth," there must be (1) complete extrusion of the child from its mother's body, and (2) some certain sign of life. The latter would be established by one or more of the following: pulsation of the cord, beating of the child's heart, motions of the limbs, twitchings of the muscles, wrinkling of the brows, puckering of the face, opening of the eyes, even if respiration does not take place. (From Witthaus and Becker's *Medical Jurisprudence,* etc.")

4. "The *general appearance* of a child that has been *born alive* at full term and respired is something like the following: The remains of the vernix caseosa are usually seen under the axilla, and behind the ears. The eyes remain partly open, and cannot be permanently closed. The ears are not so close to the sides of the head as is the case in children born dead. The hair is perfectly dry and clean, and the swelling at the back of the head (caput succedaneum) is more prominent than in the still-born. In the *dead-born* infant who has died immediately before its birth the vernix caseosa will be found, more or less, over its entire body. The eyes are closed and the ears are in close apposition to the head. The eyelids when raised close again. The mouth is closed, and from the nostrils is often observed exudation of watery blood. The hair is glued to the head. The thorax is unexpanded and flattened, and the lungs are situated at the posterior part of the thoracic cavity; they are greater in length than in breadth, and their margins are rounded; upon pressure no crepitation is elicited. Within the trachea, which is flattened, may be found a viscid mucous secretion. The remnant of the umbilical cord appears fresher looking than

that of a child that has survived its birth a few hours." (Herold's *Legal Medicine.*)

5. *Civil responsibility* refers to the responsibility which an individual has in reference to such actions as witnessing or making a will or contract, or marrying. *Criminal responsibility* refers to the responsibility which an individual has to the State for the commission of a criminal act.

BULLETIN OF APPROACHING EXAMINATIONS

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†	
Alabama*	W. H. Sanders, Montgomery	Montgomery	
Arizona*	J. W. Thomas, Phoenix	Phoenix	
Arkansas	F. T. Murphy, Brinkley	Little Rock	Nov. 11
California*	C. B. Pinkham, 929 Butler Building, San Francisco	San Francisco	Aug. 5
Colorado	David A. Strickler, Empire Building, Denver	Denver	
Connecticut*	Chas. A. Tuttle, New Haven	New Haven	Nov. 11
Delaware	J. H. Wilson, Dover	Dover	
Dist. of Col'bia	Geo. C. Ober, Washington	Washington	Oct. 14
Florida*	I. D. Fernandez, Jacksonville	Jacksonville	Nov. 12
Georgia	C. T. Nolan, Marietta	Atlanta	Oct. 14
Idaho*	O. J. Allen, Bellevue	Boise	Oct. 7
Illinois		Chicago	
Indiana	W. T. Gott, Crawfordsville	Indianapolis	
Iowa	G. H. Sumner, Des Moines	Des Moines	Sept. —
Kansas	H. A. Dykes, Lebanon	Topeka	Oct. 14
Kentucky	J. N. McCormack, Bowling Green	Louisville	Dec. 11
Louisiana	A. B. Brown, Cusach's Bldg., New Orleans	New Orleans	
Maine	P. W. Searle, Portland	Portland	July 15
Maryland	J. McP. Scott, Hagerstown	Baltimore	Dec. 9
Massachusetts*	W. P. Bowers, State House, Boston	Boston	Sept. 9
Michigan	B. D. Harison, 205 Whitney Building, Detroit	Lansing	Oct. 14
Minnesota	W. S. Pelleton, St. Paul	Minneapolis	Oct. 7
Mississippi	S. H. McLean, Jackson	Jackson	Oct. 14
Missouri	J. A. B. Adcock, Jefferson City	Kansas City	Sept. 2

Wisconsin	J. M. Beffel, Milwaukee	Madison	
Wyoming	J. B. Tyrrell, Laramie	Cheyenne	

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Auscultation of the Venous Pulse.—Josné and Gadlewski state that this procedure gives important clues as to the cardiac mechanism. While the graphic methods are more precise and scientific, nevertheless the physician with a trained ear can with profit perform auscultation of the jugular veins.—*La Quinzoine Therapeutique.*

Hemorrhage into the Right Vocal Cord, the Result of an Accident at Football.—W. M. Mollison, who reports the case of a student at Guy's Hospital who, while playing football a week previously received a kick in the neck on the thyroid cartilage, a little to the right of the middle line. He experienced a feeling of shock and of suffocation; this passed off, and he found his voice was very weak; he had, too, considerable pain on swallowing, and had a constant desire to swallow. Seen within an hour of the accident he could scarcely speak, and an examination of the larynx showed slight swelling of the right vocal cord. On attempted phonation the cords approximated but the arytenoids were not symmetrical, the right getting a little in front of the left (this is no doubt a normal abnormality in this case). Two days after the accident the voice was still weak, but normal in character, and the patient felt well, though on walking he again experienced a feeling of suffocation, but in much less degree than before. The larynx then and now showed hemorrhage into the right cord, while the left was normal.—*Proceedings of the Royal Society of Medicine.*

Miscellany.

Proverbs Relating to Diet.—There is a maxim ascribed to Theognis, according to which "Surfeit has killed many more men than famine," and Hypocrates had an aphorism that "Everything in excess is inimical to Nature." The former maxim finds modern equivalents in "Surfeit slays mae than the sword" (a Scottish proverb from Ray's collection), and a Latin counterpart in "Non plures gladio quam cecidere gula." Two other Latin proverbs put the same idea in different words: "Multo plures satietas quam fames perdidit viros" and "Multos morbos multa fercula fecerunt." A laconic adage says, "Much meat, many maladics"; an outspoken one says, "Quick to the feast, quick to the grave"; and a farseeing one announces that "Feastings are physicians' harvests." The Spanish rhyme "Mas mató la cena che curó Avicena" (The supper has killed more than Avicena cured) is a popular maxim.—*British Medical Journal.*

The Intellectual Standard of Doctors.—There is not the slightest reason to believe that physicians are linguistically inferior to parsons or lawyers. The assertion that English doctors are inferior in general culture to their French and German brethren is entirely unwarranted by facts. It is true that many of the keenest minds of the nation are attracted to fields of activity which offer a better financial return. But fortunately many men of intellect are attracted to the profession by the interest of the work, and it would be strange indeed if medical men whose education is more elaborate and costly than that of any other class of the community should have a lower intellectual standard than that of other professional men. It is recorded by Boswell that Johnson "in general had a peculiar pleasure in the society of physicians." Sir James Paget, as is mentioned in his "Memoirs and Letters," sat one evening at that very select club, Grillion's, between Gladstone and Matthew Arnold. The talk turned on professions, and Gladstone said that medicine, steadily developing and improving, was the profession of the future. Arnold said he had been much impressed in America by the superiority of the doctors over the clergy and the lawyers. As regards classical culture in particular, that is becoming more and more the appanage of a highly specialized class. Members of Parliament no longer quote Latin, and the time is long past when, as Sydney Smith said, a false quantity in early life is a stumbling-block in the career of a politician.—*British Medical Journal.*

THE STEADY SUBSCRIBER.

How dear to our hearts is the steady subscriber,
Who pays in advance at the birth of each year,
Who lays down the money and does it quite gladly,
And casts 'round the office a halo of cheer.

He never says: "Stop it, I can not afford it,
I'm getting more magazines now than I read";
But always says, "Send it; our people all like it—
The fact is we think it a help and a need."

How welcome his check when it reaches our sanctum.
How it makes our pulse throb, how it makes our heart dance!
We outwardly thank him, we inwardly bless him—
The steady subscriber who pays in advance.

A SHORT STUDY OF THE CAREER OF PARACELSUS.*

BY RICHARD COLE NEWTON, M.D.,

MONTCLAIR, N. J.

PARACELSUS (regarding the exact details of whose birth and early life there is more or less uncertainty) was the son of William Bombast von Hohenheim, who was the natural son of a Grand Master of the Teutonic Order (and, therefore, must have been a nobleman). William Bombast was a practising physician, who is said to have had a hard time to support himself and his family. He married one of the matrons of the hospital connected with the convent at Einsiedeln, near Zurich, in Switzerland, where in 1493 their only son (Phillipus) Theophrastus (Aureolus Paracelsus) Bombast von Hohenheim was born. The boy seems to have been rachitic, and was alleged to have been castrated in his third or fourth year by a hog, or perhaps a drunken soldier, or, according to another account, by his own father. The writer on Paracelsus in Baas's History of Medicine (p. 377) says that this story is most improbable, and yet adds in a note that it may have accounted for Paracelsus's repugnance for women. Hartmann says: "As a person deficient in sexual power cannot attain that high degree of spiritual unfoldment which Paracelsus undoubtedly possessed, we may, therefore, regard the story of his emasculation as one of the many calumnies invented by his enemies. It is, however, certain that no beard grew on his face, and that his skull, which is still in existence, approximates the formation of a female skull rather than that of a male."

The name given him in baptism seems to have been Theophrastus, to which he himself added other names from time to time. Paracelsus, the name by which he is most generally known, was presumably adopted to signify that he surpassed Celsus, the great medical writer of the first century, while some say that it was the result of a rude attempt to transpose his patronymic into Latin.†

Little is known of the early life of Paracelsus. He was taught by his father the rudiments of Latin, as well as more or less alchemy, astrology, and medicine. The lad was presumably precocious, and acquired knowledge quickly. He also studied with certain ecclesiastics. At sixteen he went to the University at Basel, in Switzerland, where he studied under Trithemius, and made use of the laboratory of one Sigmund von Fugger, a wealthy mine owner, where Paracelsus studied chemistry and took an active interest in mining operations. The life at the university seems to have proved irksome to him, and he left it in about two years, without taking a degree, and began wandering about over the face of the earth, even finding his way into Asia and Africa. During part of this time he appears to have acted as a military surgeon, and to have acquired that practical knowledge of the healing of wounds and of general surgery which he undoubtedly possessed. How he maintained himself during these years of wandering is not definitely known. Probably he subsisted by the practice of necromancy, and the application of alleged cures—that is, by loudly proclaiming that he had certain infallible panaceas, and bargaining with sick people and hypochrondiacs for a considerable fee before taking them under treatment.

He undoubtedly embraced every opportunity to enlarge his stock of folklore, and picked up every bit of information possible in days when books were scarce and expensive and knowledge was commonly handed down by tradition and oral instruction. He says himself that he did not read a book in ten years, and adds, "I went in search of my art, often incurring danger of life. I have not been ashamed to learn what seemed useful to me, even from vagabonds, executioners, and barbers. We know that a lover will go a long way to meet the woman that he adores. How much more will the lover of wisdom go in search of his divine mistress?"

His wanderings took him into the Orient, where he was arrested and brought before the Khan of Tartary, who promptly released him. No doubt during these journeys he added largely to his stock of knowledge of the so-called "occult sciences," and the curious beliefs and practices of the magi, sorcerers, and fakirs, scattered about among the people of India, Egypt, and Tartary.

When he was about thirty-two he returned to Germany, where his alleged great skill in the cure of all sorts of complicated and baffling maladies had become somewhat widely known. He was made city physician of Basel, upon the recommendation of Ecolampadius, the reformer, and was also appointed professor of medicine and surgery in the University of Basel at a good salary. This was in the year 1526.

He had many hearers at his lectures, which were delivered in the German tongue, a thing entirely

*Read before the Orange Mountain Medical Society, May 16, 1912.

†"The family name Bombast, probably acquired," says Mr. Browning, in a note to his famous poem, "Paracelsus," "that unlucky signification, which it has since retained, from the characteristic phraseology of his (Paracelsus's) lectures." This statement, however, does not seem to be correct, since "Bombast" in German, cognate with the Latin word *bombyx*, cotton, was the name of the cotton plant growing in Asia, and was applied also to the cotton wadding with which garments were stuffed in Queen Elizabeth's time in England. Hence it came to mean inflated speech, fustian. ("The Browning Cyclopædia," Bendoe, p. 84.)

unheard of in the universities of that day, when German *literati* were ashamed of their plain German names, and in order to appear truly learned translated them into Latin or Greek. This Paracelsus had done, as we have already seen; but either from ignorance of the Latin language or from pure bravado he continued to give his lectures and write his prescriptions in German.

Although he seemed to have been a weakly man, he was a thorough drunkard, in accordance with the custom in that time and that country. Princes, governors, and even the reformer Luther, were said to have all been true knights of the bottle. Paracelsus was unmarried and a Catholic (and was even said to have been a clerical physician under vows), in spite of his professed friendship for Martin Luther.

He was far from popular with the regular profession. In fact, he seems to have delighted in making himself obnoxious to the faculty. One of his acts, after his appointment as city physician, was to demand an investigation of the apothecaries in the town of Basel, to find out (1) whether they were competent to compound prescriptions, (2) whether their drugs were pure and correctly labeled, and (3) whether they were sold at reasonable prices.

This movement, added to the fact that he wrote his prescriptions in German, and wrote far simpler formulæ than they were accustomed to compounding, enraged the drug vendors, who were in the habit of dispensing prescriptions containing from forty to sixty ingredients, the number reaching even a thousand, prepared with all sorts of manipulations and elaborations, so that among other advantages the cost to the patient was kept as high as possible. We must admit that Paracelsus's simplified prescriptions would in these days be considered needlessly elaborated and complex; but they were far simpler than those of other physicians.

As he not infrequently made such remarks as the following about his colleagues, their feelings toward him naturally grew more and more vindictive. He said: "This is the cause of the misery in this world—that your science is founded upon lies. You are yourselves full of lies, and, therefore, all of your philosophy consists of errors and lies. You are not professors of the truth, but professors of falsehood. It is not the opinions which a person holds, but the work which he performs, that constitute a physician.

"This doctorship—this true understanding—is not conferred by emperors or popes, or high schools, but is a gift of God. I am protecting my kingdom, not with empty talk, but with the power of the *arcana* (mysteries); not with such as are bought in apothecary shops, but with the *arcana* of Nature, such as have been revealed to me by Nature herself."

In response to these somewhat uncomplimentary remarks the colleagues of Professor Paracelsus said that he was no true doctor, not having taken a degree (which seems to have been quite true); that he had disgraced the noble art of medicine by lecturing in the vernacular, and thereby letting the laity into many of the secrets of the art; that what cures he compassed he effected by the aid of evil spirits, etc.; that his character was bad, and his associates vile. It is true that his boasting had been phenomenal. He had professed to have cured thirteen princes of the blood that had been given up by other practitioners as incurable. But after coming to Basel he had had the misfortune, after having "cured" a prominent citizen, to have the man rather promptly die, a fact which his detractors did not lose sight of.

More than all these enormities, he had inexpressibly startled and shocked the "standpatters" in medicine by inaugurating his course of lectures at the University of Basel with a public burning of the works of Galen and Avicenna. He supplemented this outrage by such language as the following: "You are to be my followers, and not I yours. Me! Me! I say, you will follow—You, Avicenna, Galen, Rhazes, Montagnana, and Mesues. I shall not be your follower, but you shall be mine. You men of Montpellier, and Cologne, and Vienna, you Germans, men of the Danube and Rhine, and the Maritime Islands, Athenians, Grecks, Arabs, and Israelites—I am not to follow you, but you shall follow me; nor will any one hide even in the darkest corner, where the dogs shall not piss on him. I am to be the monarch, and the monarchy will belong to me . . .

"For I tell you boldly, that the hair from the back of my head knows more than all you writers put together. My shoe-buckles have more wisdom in them than either Galen or Avicenna, and my beard more experience than your whole academy . . . Do not boast yourself and say, 'we have Galen for our father, or Avicenna.' As for them, the stones shall fall upon them, and the sky shall produce other physicians who will understand the four elements, and magic, and the cabalistic art, that for you are only cataracts and a beam in the eye."

It does not seem unreasonable to suppose that such language would arouse animosity, and in those turbulent days might easily have led to violence.

Paracelsus is even said to have burnt a papal bull, before Luther startled the world by a similar performance. Yet in the meager personal history of the man, which I have been able to find, I do not read that he was ever disciplined by the Church, or had ever received any such document as the bull of excommunication which was issued against Luther; so that if he ever publicly burned a papal bull it was probably a mere act of bravado, and was not, as in Luther's case, a defiance of the papal authority by the contemptuous treatment of a bull of excommunication issued against himself.

However this may have been, he certainly did not need to outrage the feelings of the ecclesiastics, in addition to the doctors and apothecaries, to make himself thoroughly hated. Unless we stop to reflect for a moment, we shall scarcely realize what a serious break it was to burn in public the works of Avicenna and Galen, nor how much courage it took to defy in this way the well-crusted and thoroughly embedded mass of tradition and authority which supported those pillars of medical learning, and had done so, in the case of Galen, at least, for more than a thousand years.

To illustrate the hold which the teachings of Galen had upon the medical mind of England, I might mention the fact that in 1559, thirty years after the time of which we are speaking, a Dr. Geynes was called before the College of Physicians and Surgeons of London for impugning the infallibility of Galen, and was forced to make "a humble acknowledgment, and recantation of his errors" before he could enjoy any further privileges from the college. Gould says that for four hundred years the Greek physicians paid no heed

to smallpox, because they could find no description of the disease in the immortal works of Galen.

Hence we can appreciate the fact that Paracelsus's conduct at least required courage, a quality in which neither he nor his alleged friend Luther seemed lacking. Another quality of Paracelsus, which can scarcely fail to attract attention, is the vigor and picturesqueness of his diction. He is even said to have done much to clarify and strengthen the German language by his writing and speaking. Luther, as is well known, did a great deal to purify, strengthen, and establish the German language by his writing and preaching in that tongue, and especially by his translation of the time, as you know, preached and lectured in Latin.

After Paracelsus had been lecturing in the University of Basel for about two years he was called to a prominent ecclesiastic who was suffering from the pangs of gout. Paracelsus agreed to cure the Bible into German. Priests and doctors before his sufferer for 100 florins, and produced immediate relief by the administration of "laudanum pills," probably similar to our laudanum. He then demanded his fee, which was refused by the prudent ecclesiastic, and the matter was finally taken into the courts. The defendant not only declined to pay the bill, but publicly accused Paracelsus of necromancy, sorcery, and drunkenness. After hearing the case the court decided in favor of the priest, whereupon the professor issued a violent and abusive manifesto against the judge. This did not go well in the little republic of Switzerland, and led to the inauguration of steps to visit upon the offender condign punishment for contempt of court. The professor having got wind of this fled with great precipitation, and thus sacrificed his professorship and his position as city physician.

He went to Esslinger, where he had a house, in which some chemical apparatus was found as late as the nineteenth century, and there remained a long time—for him, probably a year or two. At length being obliged, so we are told, to go on the road again because he was in need of money, in the next ten or twelve years he went to Alsace, Nuremberg, St. Gall, Augsburg, Pfaffers, Moravia, Vienna, and Villach, always treating the sick and imparting advice by mouth and letter, always followed by pupils and students. He did not seem to take much interest in the latter, however, as he alleged that they only wanted to learn his precious secrets (arcana).

Finally, his wanderings promised to end in a peaceful existence at Salzburg, whither he went and settled down under the protection of the Prince Palatine, Duke Ernst of Bavaria. Even here his stay did not last long, for he died at the "White Horse," presumably a tavern of more or less repute, September 24, 1541. Some say that he died from disease, and others that he was thrown down a cliff or otherwise maltreated by hired assassins, emissaries of doctors who hated him, and still others that he fell and fatally injured himself while grossly intoxicated.

After his death an inventory of his effects was made. He seems to have left very little behind him, especially very few books. "His whole library consisted of a Bible, a biblical concordance, a commentary to the Bible, and a book of medicine in manuscript."

Thus passed away a remarkable man, whose influence on the history of medicine was very great. If you will bear with me, I will try to give you a few extracts from his teachings, and will quote a few opinions concerning his character and achievements, because I believe that these will not be without value in our endeavor to get a glimpse of the state of medicine at that period of its history.

It must be borne in mind that this peculiar man read very little and wrote very little himself. His alleged writings were mostly the work of his pupils, and seem to have often been carelessly and incompletely done. A great quantity of manuscript was turned over to the printer after his death, which was alleged to be the authentic teaching of Paracelsus. A great deal of it must have been spurious, and of the authenticity of a great deal of the autograph writing there may well be much doubt, especially as direct contradictions appear in his statements upon the most superficial examination; and by reason of his habits and his vagabond way of life, one could hardly expect that he would leave behind him a careful, complete, and methodical collection of manuscripts.

Dalton[2] says, "He even gloried in his ignorance, and considered it as evidence of originality; he was wont to say, 'My own writings are enough to prove this, for in this book I shall bring forward not less than six hundred new inventions. Not one of them is admitted by any philosopher or physician, ancient or modern, unless he is willing to abandon the writings of the ancients altogether. There are plenty who know that my whole library is so small that I could hardly make out of it a dozen written pages; and, besides, my secretaries will testify under oath that they have written everything from my own dictation.'"

Antiprassus Siloranus (Hartmann[1]) says that Paracelsus wrote thirty-five books on medicine, two hundred and thirty-five on philosophy, twelve on politics, seven on mathematics, and sixty-six on necromancy; but as he was engaged in literary labors for only about fifteen years, as Hartmann tells us, it would seem impossible for him to have written so many books.

John Huser made a careful collection of the works of Paracelsus, which was published in 1589-90. This was in eleven quarto volumes, containing one hundred and six titles, many of which were short articles and letters, while there were a number of formal treatises. He coined a great many words to express his meaning, so many indeed, that it is almost, or quite impossible to understand much of his alleged writing. Of course all alchemical writing contains many obscure and curious words and phrases. But Paracelsus had improved on his predecessors in the skill with which he could mystify his readers and hearers. This seems to have been a part of his game of alchemy.

His disciples, Dorn, Thureyssen, and Ruland, composed dictionaries to define these curious terms. Of these the one compiled by Ruland, entitled "Lexicon Alchemicum," Prague, 1612, is the most complete. This was republished in London in 1660, so Hartmann tells us, by Guilhelinus Johnson, under his own name, and has been incorporated into the "Bibliotheca Chymica Curiosa," by J. T. Mangets, Geneva, 1702. Another, "Dictionarium Paracelsicum," was written by a certain Bailiff, and added to the Geneva publication.

Speaking of the alchemists, Professor Dalton says by the sixteenth century this embryonic science (alchemy) "had become largely tinctured with

charlatanism. The writers on alchemy used the strangest terms to describe chemical substances, and employed various signs to designate them, which were not always the same for the same substance."

Thus gold was represented either by the sun, the lion, or the swan; silver by the moon and the owl; copper by Venus; iron by Mars and the wolf; tin by Jupiter, the eagle, and the stag; and lead by Saturn and the mole. Traces of this practice still exist in our own materia medica, as when we use the term "lunar caustic" for nitrate of silver, or "saturnine preparations" for salts of lead.

To quote further from Dalton's excellent paper, "One of their most singular freaks was the general habit of using this studiously obscure language in order to guard their secrets from discovery, even by the reader. It is not easy to comprehend why if an alchemist wrote a book to teach us how to make the philosopher's stone he should not tell the story so that we could understand him; or, on the other hand, if he did not wish his secret to be known, why should he write a book about it at all? But, as a matter of fact, this was a very prominent feature of nearly all the works on alchemy.

"Paracelsus, of course, was an alchemist, and has much to say about the production and virtues of the great elixir. He claimed to be superior to the other alchemists, and to have more efficacious means of success. Here is 'A quick and easy way to make a philosopher's stone.' The old spagyrites (alchemists) would not have needed to go through all this labor and tedious reiteration if they had studied in my school; they would have accomplished their object equally well, but at far less trouble and expense. And now, at this time, when Paracelsus is the monarch of the *arcana*, the period has arrived for that discovery which, before me, was hidden from all the spagyrites. Wherefore, I say, take only rose-colored blood from the lion and glue from the eagle, and after you have mingled them together, coagulate them according to the old process. You will then have the philosopher's tincture which men without number have sought for but very few have found."[3] Dalton continues: "If we try to interpret this lucid prescription, we should remember that 'lion' is one of the cabalistic synonyms for gold, and the 'eagle' one of those for tin. If gold be dissolved in nitromuriatic acid, evaporated and heated, and the product dissolved in water, it forms a solution of the terchloride of gold. This was probably the alchemist's 'rose-colored blood from the lion.' On the other hand, protochloride of tin, which is a gray, resinous looking, and easily fusible substance, was perhaps what they called 'glue from the eagle.' It will precipitate the gold from a solution of its terchloride, in the form of brown powder."

The receipt of Paracelsus, if translated into modern language, would then read as follows: "Take only a solution of terchloride of gold, and a solution of protochloride of tin, and coagulate them—that is, make a precipitate by mixing them together. We should thus have, at the end of the operation, the same gold, in a different form, which had first been dissolved in the nitromuriatic acid." Now that we have the precious article, however, it seems that it is not quite ready for use, according to Paracelsus, and the operation which still remains necessary can hardly be called an inexpensive one.

"If the philosopher's tincture," he says, "is to be used for transmission—a pound of it is first to be projected over a thousand pounds of melted gold; thus, at last, the medicine will have been prepared, which is able to transform the leprous humor of the metals.

"Of all the *arcana*, or occult remedies, which Paracelsus depended on in practice, the most valuable was his 'Quinta Essentia,' or fifth essence, which he extracted from all sorts of substances, animal, vegetable, and mineral. He considered this quintessence as containing, in concentrated form, all the life, power, and occult medical properties of the substance from which it was derived. Some of these were of extraordinary virtue. For example, he said that the quintessence of pearls, extracted by himself, had such power that with it he had restored to life and strength men who were already in the agony of death.[4] Of course, the quintessence of gold was more valuable than any of the others, and his process for extracting it is a fair sample of laborious and fruitless prolixity of the operation of the alchemist."

The formula is as follows: "Take pure gold, reduced to the smallest grains, and rubbed into a powder with plumbago. Add to this of the best white wine that can be procured one hundred parts, and white resin of the pine ten parts, and macerate in a glass vessel forty days. Pour off the wine, add the same quantity over again, and macerate as before. Repeat this a third time. Then take all the wine from the three successive macerations, place it in a glass vessel, well covered, and distil with a strong fire, so that it may come over rapidly. When the distillation is complete, place the liquid in a glass vessel, well covered with a blind alembic, upon a bed of ashes, hot enough to burn the hand.

"Keep it in this condition until nine parts of the liquor are consumed or dried up, and only the tenth part remains. To this remaining liquid add an equal quantity of the white of egg, shake the mixture and distil together. At first, distil slowly, and a white liquid will come over, which should be set aside. Then increase the heat until the vessel is red hot, when there will come over a material of thin, honey-like appearance and strong odor. Keep this; for it is the fifth essence of gold, and a royal medicine."

In reality, this substance would not contain the least particle of gold, or of any of its derivatives.

Paracelsus was also an adept in the cabalistic signs so greatly in evidence in the medical and alleged scientific writing of the day, and was especially strong in the so-called doctrine of signatures. Dalton calls this "the most senseless and futile of the many delusions of the period." It was the alleged science of supposed correspondence and sympathies in Nature; the macrocosm and the microcosm, or the imaginary relations between the planets and terrestrial objects. As, for instance, the seven great organs, the brain, heart, lungs, gall, kidneys, and spleen, were assumed to correspond to Moon, Sun, Mercury, Mars, Jupiter, Venus, and Saturn.

Diseases also, in their quality as integral parts of the microcosm, like microcosm in microcosm, have their models in the macrocosm.

Thus epilepsy resembles the earthquake; apoplexy the lightning; flatulence the wind-storm; dropsy, inundations; the chilliness of fever, the quaking at the origin of a new world; while intermission of the pulse corresponds to the eclipse, etc.

The cabalistic doctrine also applied to external marks of form, color, or consistency, by which their occult sympathies or relations were supposed to be indicated. These signatures were more or less vague and imaginary, when applied to treatment, at least in most cases. For instance, saffron from its color was esteemed a valuable remedy in jaundice, bloodstone for hemorrhage, and red cowes for blood diseases. Ginseng and mandrake roots from their shape were supposed to be tonic and aphrodisiac, and the whole family of the liverworts were so named because they resembled roughly the liver in shape.

It is easy to see how speculation along these lines might suggest the great motto of homeopathy, "like cures like." Butler says in Hudibras,

> "Seek out for plants with signatures,
> To quack of universal cures."

This foolish doctrine exercised an enormous influence upon the medicine of the time.

I quote from Wilder[5] Paraselsus' own definition of the doctrine of signatures. "This signature, or specific indication, is a certain organic vital activity giving to each natural object a certain analogy to a certain condition produced by disease, and through which, in specific diseases, health may be restored in the diseased organisms."

Wilder, after praising the clarity and completeness of the definition, goes on to say: "This hypothesis, it will readily be perceived, underlies the doctrine of homeopathy, and the dogma of direct and specific medication." This may be so, but it is a little difficult for a non-inspired thinker to see the connection, or to be satisfied with the definition.

Our physician was also addicted to the modern device of practising "both ways"; for he held that one should be willing to cure not only with opposing remedies, like the ancients, but also with similar remedies; not only *contraria contrariis*, but *similia similibus*—a motto so strongly emblazoned on the escutcheon of a modern sect of practitioners. Paracelsus held that "wherever there is a new disease, there is also its remedy." He also held peculiar doctrines regarding the composition of the body, assuming that men are made up of three principal ingredients—salt, sulphur, and mercury. External diseases, in his view, are diseases of the elements, salt and mercury, while most fevers and internal diseases are diseases of the sulphur.

He is said to have been the first to make use of the magnet for the treatment of disease. He taught that the so-called *archaeus*, or primordial life-essence, was distributed to all parts of the human body, and that it was of a magnetic nature, attracting or repelling other sympathetic or antipathetic forces, belonging to the same plane. The vital force is not inclosed in a man, but radiates around him like a luminous sphere, and it may be made to act at a distance, etc. Again he says: "The invisible forces, acting in the visible body, are often very powerful, and may be guided by the imagination and propelled by the will. This, he thought, was accomplished by the principle which he denominates *mumia*. This is the vehicle of life," etc.

He was strongly in favor of employing the magnet itself for healing purposes, and gives explicit directions for its use. He pretended to know the powers of mineral, human, and animal magnetism. He is said to have been the originator of the peculiar doctrine, afterward claimed and exploited by Mesmer, in that elaborate system of quackery called mesmerism. He speaks of hydrogen as an element, and is said to have known of the existence of nitrogen and oxygen, to quote Dalton again. His idea was that medicine is a mixture of astrology, alchemy, and mysticism. Anatomy seems hardly capable of being treated in this way, and yet his anatomical notions may be judged by the following description of the eyes, taken from his chapter "De Anatomica Oculorum." He speaks of the substance, the material, and the form, of which the first is from without; the second from within; and the form is in both.

"First, *Substantia*.—The eyes are twins; that is, two fruits, or products, joined in the form of a cross, with reference to a center, in order that they may have, as nearly as may be, the same integral composition. They are united in the middle, and thence look downward with the stem and upward with the root. These trunks give off no branches, but only fruit; that is, they produce a blossom, which has material, and bears fruit, which is the sight.

"The flower is white; the fruit is purple, and each of them has a bark, which forms the tunics and the root. In the pith is situated the sight; that is, the substance of the eye.

"Second, *Materia*.—The material consists of three things; viz., sulphur, salt, and mercury. (As just said, according to Paracelsus, these three substances are the ingredients of everything.)

"Sulphur is the flower and fruit, in all colors, according to the mode of resolution, outside the visual body. The visual body is Mercurius, in which is contained imperfect sight, without any other material.

"Salt is the solidification of both, since it reduces the parts into one form; that is, it completes the essence of the visual body.

"Third, *Forma*.—The form is that of a cross, because the central part bears twins. Afterward, each twin passes into its own form or rotundity; since the eyes in the body fill the place of the Sun, as in a microcosm."

From this romantic description of the eyes we learn that Paracelsus did not understand by "anatomy" a description of the internal structure of an organ, but a fanciful enumeration of vague similitudes and analogies, which are more ingenious than instructive.

The titles to the chapters of his books show a large proportion of similar subjects, as, for instance, "On the Mystery of the Mycrocosm;" "The Philosophy of Theophrastus, of the Generation of the Elements;" "On the Occult Philosophy;" "The Treasury of Treasuries of the Alchemist;" "On the Fifth Essence, or *Quinta Essentia;*" "On Magisteria;" "On Specifics or Elixirs," and "On the Signatures of Natural Things."

He pretended to have a remarkable power of perception and diagnostic skill. According to him, "A man's body ought to be to the physician as transparent as the distilled dewdrop, where not the slightest particle can escape the sight. The eye of the physician ought to penetrate through a man's body as it would through a limpid and sparkling fountain, where he can distinguish every pebble and grain of sand with its natural shape and color; . . . all the members of the body ought to be as transparent within as a polished crystal, where not even a hair could be concealed without his knowing it."

"Opium (which, as Dalton avers, no school of practitioners seems able to dispense with) was one of the few older remedies which he retained in his pharmacopœia. His specifics and essences of various grades were some of them inert, but others were very powerful, and he seems to have used them all indiscriminately, without much caution or intelligence."

I cannot forbear at the risk of making this paper too long, to quote in full a letter from Theophrastus Paracelsus to his good friend, the most learned chief of theologians, Erasmus Roteradamus.

"What the learned Muse and Alstoos (probably referring to Frobenius, a grateful patient of Paracelsus) and some other person have attributed to me in medicine, really belongs to me. I am certainly the author of these opinions The region of the liver (in your case) does not need any medicine, nor do your two other complaints require laxatives. The medicine for you is *Magistrale,* an *arcanum,* extracted from a strengthening specific, and obstersive; that is to say, consolidative syrup. For the troubles of the liver it is a second essence, and in gravel of the kidneys it is esteemed a royal medicine. I know that your system cannot bear colocynth, nor any disturbance, or at any rate very little from purgative drugs. I know that I am more clever and skillful in my art than that, and I know what in your system will secure a long, quiet, and healthy life, and that you do not need evacuations. Your third disease (to speak plainly) depends upon a matter of some kind, either an ulcerated putrefaction or phlegm, perhaps produced on the spot or accidentally collected, or else the excrement of the urine, or the tartar of a vessel, or mucilage from other parts of the sperm, or a vicious or bituminous state of the blood. It is a liquid gravel, coagulated by the potency of salt (in which the coagulating power resides), as it is in flints or beryls. This is the way it is generated, and I have seen it in your case. But whatever I have decided on I have made up my mind that there are calcareous mineral grains in the kidneys under the form of coagulated matter. If my specific practice, O excellent Erasmus, should please your excellency, I will take care that you have both a physician and a physic. Adieu,

"Theophrastus."

Who can wonder that after this lucid exposition of the case, Erasmus, one of the most learned men of his time, was duly impressed, and says in his letter of reply: "I am surprised at your knowing my case so well, after having seen me only once."

Paracelsus exercised a great influence upon the theory and employment of mineral springs (particularly those of Pfeffers, Gastein, etc.), and it is one of his chief services that he subjected the learned medicine of his day (which thought itself safe only in guilds and study-rooms) to the test of living observations and actual life, and employed chemistry in medicine, particularly also as it related to the question of mineral springs. As the science of chemistry itself was improved, the subject of mineral waters likewise enjoyed increasing attention.

In the treatment of wounds Paracelsus had excellent ideas (Walsh[6]). Nature, he said, produces the means of union in a viscous exudation, or natural balm. He also most bitterly denounced the surgeons for allowing wounds to remain dirty and for undertaking needless operations. He, therefore, deserves credit as a reformer of surgical practice. "The high value of his surgical writings," says Hoxer, "has been recognized at all times, even by his opponents. . . . His description of hospital gangrene is perfectly true to nature; his observations on syphilis are also sound and sensible, and he was the first to point out the connection between cretinism of the offspring and the goiter of the parents. . . . He avowed the highest respect for the teachings of Hippocrates, while he discarded the practice founded upon the writings of Galen, Rhazes, and Avicenna."

Speaking of the then prevalent practice of medicine, he said: "All that they (the doctors) can prudently do is to observe the patient, and make their guesses about his condition; and the patient has good cause to rejoice if the medicines administered to him do him no serious harm and do not prevent his recovery. The best of our popular physicians are the ones who do the least harm. But unfortunately some poison their patients with mercury, and others purge or bleed them to death. There are some who have learned so much that their learning has driven out all their common sense, and there are others who care a great deal more for their own profit than for the health of their patients. . . . A physician should be the servant of Nature, not her enemy; he should be able to guide and direct her in her struggle for life, and not throw, by his unreasonable influence, fresh obstacles in the way of recovery."

Paracelsus also said, "The knowledge of Nature is the foundation of the science of medicine," and it is taught by the four great departments of science, philosophy, astronomy, alchemy, and physical science." By "philosophy," he meant the true perception and understanding of cause and effect. For skill in this department of medicine he maintained that the physician "must, above all, be in possession of that faculty which is called intuition, and which cannot be acquired by blindly following the footsteps of another. . . . If you wish to be a true physician you must be able to do your own thinking, and not merely employ the thoughts of others."

By "astronomy" is signified the mental sphere of the being. The influences of the seasons, heat and cold, dryness and moisture, light and darkness, are also included. "Man's diseases do not originate in himself; they originate from the influences which act upon him and enter his constitution. If the air becomes vitiated it may poison man's body; if the astral influences are in a state of corruption they may do likewise." A pleasant blending of climatology and astrology seems evident under the above head.

He continues: "To be an alchemist is to understand the chemistry of life. Medicine is not merely a science, but an art; it does not consist in compounding pills and plasters and drugs of all kinds, but it deals with the processes of life, which must be understood before they can be guided. A powerful will may cure, where a doubt will end in failure. The character of the physician may act more powerfully upon the patient than all the drugs employed. The physical surroundings of the patient may have a great influence upon the cause of his disease. If he is waited on by persons who are in sympathy with him it will be far better for him than if his wife or attendants wish for his death. He (the physician) should know

how to regulate the diet of the patient." After these sensible remarks our great man wanders off into those realms of superstition and pseudoscience where a jargon of words obscures the writer's meaning, if indeed he can be said to have had one.

After this somewhat disjointed and fragmentary exposition of the teachings of Paracelsus, we can draw certain conclusions. One is that he seemed to believe and teach almost anything that was going, if he could thereby discredit and antagonize the regular profession. He contradicted himself, and at times talked what seems to us gibberish; but for all that, he blazed the way for a more rational and sensible medical practice. He insisted on the observation of Nature, and declined to believe or practice anything, just because it was old. He taught manliness and truth whether he practised them himself or not.

His motto was "*Qui suus esse potest, non sit alterius,*" which will bear the translation, "Who is able to be his own man, should not be another's."

He professed to seek help and guidance from every possible quarter; he asserted "If God will not help, so help me the devil." Speaking of devils, he was wont to tell his patients that he carried a small devil imprisoned in the hilt of his sword, and he no doubt derived some inspiration from this, as when deep in his cups he would retire to bed without undressing, and would lie there wildly waving the trusty weapon.

He preached strongly and effectively against the senseless polypharmacy of his day. He demanded a chemical examination of the urine, instead of the senseless gazing at a sample of it in a vial for inspiration in making a diagnosis, which had long been a custom with physicians (seichbesehen, Paracelsus termed it). He turned the thoughts of the profession and the laity to the invaluable aid which chemistry has been able to afford in the preparation of remedies, and foreshadowed the supremely important part which this branch of science is at last playing in solving the problems of physiology and nutrition. It does not detract from this claim to assert that, in his time, scientific chemistry was unknown. He took a great step forward by turning attention to the fact that in the development of this branch of natural science lay the hope of the discovery of many valuable remedies, and much transcendently important knowledge of the body and its functions and development.

He insisted in moderating the then all-prevalent practice of phlebotomy. He used mercury in the treatment of syphilis, and discarded the popular abuse of regimen during the treatment. He insisted on keeping wounds clean, and forbade all useless surgery.

Such a man cannot be dismissed with a few phrases. In point of fact, for nearly four hundred years he has held a prominent place on the medical stage. Perhaps I cannot sum up in better fashion than to quote Dr. Dunster, who said in 1872 (Dalton[2]), "We cannot, therefore, refuse an acknowledgment of gratitude to Paracelsus, that magnificent charlatan, who struck at 'authority' the blow whose influence is felt even down to our day, and which shook the medical throne of Galen and Avicenna to its foundation."

EXPERIENCES WITH THE ABDERHALDEN TEST IN THE DIAGNOSIS OF PREGNANCY.

By JACOB GUTMAN, M.D.,
BROOKLYN, N. Y.
DIRECTOR PATHOLOGICAL LABORATORY, JEWISH MATERNITY HOSPITAL,
AND
SAMUEL J. DRUSKIN, M.D.,
MANHATTAN, N. Y.
ASSOCIATE SURGEON, JEWISH MATERNITY HOSPITAL.

It would seem reasonable to assume that the diagnosis of a physiological process such as pregnancy, occurring since the very origin of human life, would not be surrounded by any particular difficulties. Its common everyday occurrence presents numerous opportunities to the practitioner to familiarize himself thoroughly with its various pathognomonic signs. These signs ought to suffice to prevent errors in diagnosis, and yet such mistakes are not infrequent. Were these errors limited to the earliest period of gestation, an excuse for their occurrence might perhaps to some extent be justly advanced, but it is not at all uncommon to find cases of pregnancy as far advanced as the sixth or seventh month mistaken for some other condition. Unfortunately, in quite a number of cases, conditions may be so complicated that a correct diagnosis may be extremely difficult, but in just such cases, on account of the bearing it may have upon the proper subsequent management of the case and its prognosis, it becomes imperative to decide definitely. The difficulty arises especially when a differentiation between pelvic tumors, diseased adnexæ, ovarian new growths, cystic formations, etc., is to be made from a normal pregnancy. Many an abdomen has been opened for suspected pathological conditions of the generative organs to find only a normal pregnancy; even hysterectomies have been performed for supposed fibroid tumors to find present, on further examination, nothing more than a condition of normal pregnancy. Such mistakes have to be prevented absolutely, positively. Therefore, any discovery which tends to improve our present methods of diagnosis of pregnancy, early or late, is a welcome addition to our present knowledge of this subject. Especially valuable is the acquisition of such methods whereby the personal equation of the examiner may be eliminated or restricted; such tests as will be sufficient in themselves and independent of particular skill of the individual examiner. Likewise it will be of inestimable benefit to have any tests as definite as most of the chemical tests of the other branches of medicine, such as uranalysis. It is evident, therefore, why the latest discoveries of Abderhalden[1] concerning the diagnosis of pregnancy by specific serological means has attracted much attention from numerous workers of both continents. The interest it has awakened is amply demonstrated by the number of articles published upon the subject in the short time since its first announcement by the discoverer, Emil Abderhalden.

The Principles of the Test.—The biological pregnancy test of Abderhalden is based upon the fact established by Veit, Weichard, and Schmorl, that

at certain periods of gestation detached chorionic cells are found floating in the maternal circulation. This occurs during the development of the placental chorionic villi, their penetration into the maternal tissues and the formation of intervillous spaces. The proteins of the above-mentoned chorionic cells are different in their composition from those of the mother and foreign to the organism in whose circulation they are floating. The maternal organism reacts against this invasion by a foreign protein with the production of a specific proteolytic ferment. The latter destroys the invader by decomposing it into its primitive or fundamental constituents. These primitive building stones are then utilized for the reconstruction of proteins peculiar to the maternal organism. The purpose of such transformation is wholly a protective one; it shields the maternal organism from the deleterious effects of proteins foreign to it. The ferments concerned in the disintegration of the more complicated, higher, non-dialyzable albumins of placental tissue into lower, less complicated, dialyzable substances are to be found only in the blood of those individuals in whom chorionic cells are circulating, *i.e.*, those of pregnant women, and especially in the earlier months of pregnancy. The blood of others does not seem to possess these qualifications. The trend of opinion of the greater number of investigators (Frank and Heiman,[2] Franz and Jarisch,[3] Schlimpert and Hendry,[4] Freund and Brahm,[5] Williams and Pearce,[6] McCord,[7] Epstein[8] and others) up to the present time has been toward substantiation of this principle, and with the exception of a few (Engelhorn,[9] Lindig,[10] Polano) the latter has been corroborated and accepted as true. The enzymes so engaged are not strictly limited in their action toward the proteins inducing their origin or appearance, but also destroy related proteins, although not as readily. They have no effect, however, upon proteins of other species or varieties, upon carbohydrates, etc.

Our Experiences.—Having recognized the value of the test and having been impressed by the remarkable results obtained by Abderhalden and his co-workers,[11] we undertook the study of this test to verify the results. We were especially favored by the rather abundant material suitable for such purpose as presented itself by a maternity hospital (Jewish Maternity Hospital, New York City). In addition our own private practices were drained as much as possible for suitable cases, and a number of blood specimens were obtained from our friendly colleagues, to whom we are greatly indebted for their kind cooperation.

We began our work several months prior to the latest publication of Abderhalden, in which he again details exact directions for the test and pleads for absolute adherence to them. We stumbled in a great number of our experiments again and again upon numerous difficulties, which we were at first unable to explain or correct. Oftentimes the findings proved contrary to our expectations and contradictory to the reports as published by the originator of the test. Had we been guided by our own findings exclusively and not swayed by the deference due to the statements of an authority like Abderhalden, perhaps a number of these incorrect findings would have been interpreted by us as correct, and an error thus committed. For this reason we were induced frequently to retrace our steps, study the discrepancies, and seek for their causes. A thorough analysis of all procedures, a careful examination of all substances utilized in the performance of the tests would usually reveal the causes of the discrepancies, and accurate results could thus be recorded.

We concur, therefore, fully with Abderhalden and others who insist upon absolute exactness of all procedures and the most scrupulous adherence to prescribed rules, as the correctness of the results obtained depends entirely upon the mode of procedure. During the later part of our experimentation, after we had been properly trained in the technique, we were unable to record even a single failure, as our reports will further show. We must repeat, therefore, that only absolute accuracy, closest attention to minute details, repeated controls, and exact technique will result in thoroughly reliable data.

The number of our cases comprises in all 202, upon which 357 tests were performed. The greatest number consisted of applicants to the Jewish Maternity Hospital. These were cases of pregnancy of the later months, from the sixth to the eighth. Very early term pregnancies were unfortunately few at our disposal, the earliest one having been nine days overdue and probably three weeks pregnant. A number of tests were also made from blood obtained during deliveries of the same patients, while some tests were performed postpartum. A number of experiments were also made with blood from various sources, from placenta, uterus, cubital vein, etc.; in others various modifications were employed for study and comparison. To detect dialyzable substances we used the chemical methods (biuret and ninhydrin) exclusively, as the optical is much more complicated and its equipment expensive.

Because of the variability of methods and different modifications conducive to variable conclusions, we had to divide the above tests in a number of groups. Some of these we had to disregard, because of our faulty technique and inexperience, while the others in general showed a satisfactory percentage of correct results, varying but little from each other, although different methods were employed in each group. In one of these, for instance, which consisted of twenty-four cases, five non-pregnant and nineteen pregnant, from the fifth to the eighth month of pregnancy, and in which well-prepared placenta, collodion fuchsin stained dialyzers and the biuret test were employed, 92 per cent. of correct findings were recorded. In another group of thirty-seven cases in which the same placenta and dialyzers were used, but the biuret was substituted by the ninhydrin test, 95 per cent. correct answers were obtained. In the last and largest single group, consisting of 106 cases and 159 tests, in which we strictly adhered to the methods to be detailed later, 98 per cent. correct findings were obtained. This last group deserves fuller description and explanation.

Of the 106 cases of this series tested 79 were those of pregnancy and 27 non-pregnant; of the latter, 11 males and 16 females. The male number comprised the following cases: 3 normal individuals, 1 gastric ulcer, 3 gastrointestinal catarrh, 1 osteosarcoma, 1 neurasthenia, 2 syphilitics (with positive Wassermann). With the exception of one of the syphilitic sera, all sera gave perfectly distinct and unmistakable reactions, negative as to pregnancy. The above-mentioned syphilitic case, one of the two unfavorable findings of this series, gave an indistinct biuret and a doubtful ninhydrin

reaction. In both syphilitics the sera in the control tubes (without placenta) upon boiling with the ninhydrin solution gave strongly violet colorations. A certain amount of violet coloring was noticed in a number of sera when tested with ninhydrin, but none seemed so exceptionally deeply colored as those with the positive Wassermann. The diffusate of one of these cases was of the same color as the control, but the diffusate of the other syphilitic resulted in a darker colored reaction with the ninhydrin, and had to be pronounced as doubtful or mildly positive. When diluted with distilled water it required nearly one-half the amount to equalize its color to that of the control. Unfortunately, we did not have sufficient serum to repeat the tests so as to assure ourselves as to its correctness.

Of the 16 non-pregnant female patients, 2 had gonorrhea, 1 chlorosis, 4 endometritis chronica with displacements or prolapsus, 1 ovarian cyst, 1 carcinoma uteri, 2 tuberculosis pulmonalis, 1 menopause, 2 enteroptosis, 1 chorea, and 1 hysteria.

All of these gave perfectly negative results for pregnancy and thus were interpreted correctly by the tests.

The positively pregnant cases of this group numbered 79; 6 up to third month, 21 from the third to the sixth month, and 52 from the sixth to the ninth month of pregnancy; 9 of these cases were in addition examined postpartum, five during delivery. Primiparæ were 15, multiparæ 64. Noncomplicated or normal cases were 71, complicated 8, of which 3 were ectopic, 1 uterus didelphus, 3 with pulmonary tuberculosis, and 1 postoperative (for sterilization). The cases were either delivered at normal term, or attended for abortion, or operated. In 78 of the 79 cases the results were absolutely perfect, having obtained more or less distinct positive reactions, some more strongly than others, but in one case, a case of ectopic with following laparatomy, the test resulted negatively. This case and the one cited previously (the syphilitic) constitute the only disappointments of this series, otherwise the results obtained were perfectly satisfactory in every detail.

Of the 159 tests employed for this series of cases 12 were made with collodion dialyzers only, 23 with collodion and Schleich and Schull's diffusion sacs, the rest with the latter dialyzers alone. The two kinds of diffusion condoms worked satisfactorily, although the imported variety (Schleich and Schull's) gave stronger reactions with the ninhydrin solution.

Every dialysate was tested with ninhydrin, in 34 cases the biuret test was also applied for comparison; 27 were distinctly as positive as the ninhydrin, in 7 less definite or uncertain. The diffusates gave a strong reaction in 128 tests, less prominently in 23 and absent in 4 (biuret) tests.

The Technique of the Test.—The tests of the above-described series of cases were performed strictly in accordance with the following procedures, which we believe are the proper ones to employ:

Preparation of Placental Protein.—A perfectly fresh, normal placenta (should be fresh in order to avoid possible contamination by bacterial fermentation) should be rinsed for an hour or two in running hard water and then irrigated through its cord vessels with several more liters of water until the placenta becomes quite colorless or perfectly bloodless. To facilitate the process irrigation with saline solutions (0.5 to 0.9 per cent.), as recommended by Schlimpert and Hendry, will make the placenta bloodless in about half an hour. The latter is then freed from the adhering membranes, its fetal surface and as many of the fetal blood vessels as possible. The placenta is then cut into small pieces (cubic inches or more), which are again washed and squeezed out (best done with a Boas sieve) and put into a vessel with distilled water to boil for one hour. The liquid is then poured off, fresh water added and boiled again for five minutes more. The fluid should remain clear and colorless, and if tested for protein bodies by the ninhydrin or the biuret methods a negative result should take place. If the contrary or a doubtful reaction is obtained, the boiling must be repeated with fresh water until the tests result negatively. The placental pieces are then removed, placed in a sterilized wide-mouthed vessel containing distilled water and chloroform, and the whole covered with a layer of toluol of sufficient thickness (from ½ to 1 inch thick) to insure against the invasion of bacteria and evaporation. Before utilizing the placental pieces for the test proper they must again be tested for the presence of low-grade proteins that may have appeared during preservation. This is done by boiling them for one minute in about five times their quantity of sterile water. Passing the fluid through a hard filter the filtrate must be tested for albumins by the ninhydrin test. The latter must result negatively; otherwise the placental pieces should not be employed for the biological test proper.

The Dialyzers.—As a dialyzer Abderhalden and others advise the use of Schleicher and Schull's condoms, No. 579, or better, No. 579 A. The latter are supposed to be specially prepared for this purpose, but we were unable to obtain them here and were limited to the use of the No. 579 variety. While this kind of dialyzers is perhaps the best obtainable for this use, yet full reliance should not be placed upon them, and they should only be used after having been tested as to their permeability toward albumins and peptones and for imperfections. A considerable percentage of the dialyzers may thus be found defective; out of 25 in a box we found at one time as many as eight unsuitable. The good ones may be used repeatedly, but one must always be on guard for imperfections, for sooner or later they are liable to become defective.

In a large number of our tests we have employed also condoms prepared from collodion (U.S.P.). Medium sized test tubes, three quarters of an inch in diameter and four to five inches long, were lined with a layer of collodion, stained with a little dye, such as fuchsin. Another coating was applied before the first was entirely dry. Both coatings were permitted to dry and shrink. If the test tubes have previously been scrupulously cleaned the condoms come out most perfectly and make reliable dialyzers. They should be preserved in water and used only once. They are cheap, not very difficult to manufacture, and seem to serve the purpose. A dialyzer prepared and specially tested for the serological pregnancy test of Abderhalden has now been placed on the market by the firm Schoepps in Halle. We have not been able to procure these dialyzers in this city up to this time.

The Preparation of the Serum.—The blood should be obtained from the patient, upon an empty stomach, preferably in the morning, at a time when the blood is most free from possible contamination

by low grade proteins due to a meal overabundant in proteins. Ten c.c. of blood should be drawn with a dry sterile needle and left for half an hour at room temperature to clot firmly. The clot is then separated from the walls of the container with a platinum needle to permit its sinking to the bottom. In separating the clot from the serum care must be taken not to break up the red blood corpuscles to avoid contamination with hemoglobin and their lysis by hemolytic ferments. Centrifuging is not advisable. The test tubes and contents are then put in a cool place until ready for use. They may remain for twenty-four hours or longer, if kept on ice, without detrimental effects on the test. Of this serum, which must be perfectly clear, three c.c. are used for each test.

The Ninhydrin Test.—The ninhydrin or triketohydrinder-hydrate reaction is always to be preferred to the biuret test. First, it reacts not only with *very minute* quantities of peptones but also with the products of their further decomposition, all amino-acids containing the acid amino group in the alpha position to the carboxyls. This permits of a larger number of dialyzable substances to be tested for, not all of which are detectable by the biuret test. Perhaps, therefore, we were enabled in some cases to obtain positive reactions in which the biuret reaction was indistinct if not negative. Second, because the whole volume of the fluid tested becomes colored, while in the biuret test only a faint ring appears to serve as a guide.

The contents of the tiny vial of ninhydrin, as marketed by the manufacturer, is dissolved in ten c.c. of distilled water, thus making a one per cent. solution. For each test 0.2 c.c. of this solution is added to 5 c.c. of the liquid to be tested and boiled from one to five minutes over a water bath. In our experience, one minute's boiling, as advocated by some experimenters, did not always suffice to induce a reaction, and in numerous instances a positive reaction appeared only after five minutes. The recording should be done half an hour after cooling and always and only by comparison with the controls. As the ninhydrin solution is dichrotic, only the violet color by translucent and not the pinkish by transmitted light should be considered in declaring the results positive. We wish to emphasize the fact that the quantities of ninhydrin solution added to the serum and controls must be measured with the utmost exactness, for unequal quantities will produce inaccurate reactions.

The Biuret Test.—There are a number of ways of performing the biuret test for peptones. In our experiments we employed it in the following manner: Fifteen to twenty drops of a twenty per cent solution of copper sulphate were diluted with 250 c.c. of distilled water. Pure colorless twenty per cent. solution of potassium hydroxid was used as the alkali. To 10 c.c. of the fluid to be tested three c.c. of the alkaline solution was added, shaken, and carefully stratified with the copper solution. In positive cases a very distinct and unmistakable violet ring separated the two liquids.

The Technique of the Test Proper.—A piece of placenta, the size of a pea or bean, weighing about one gram (a larger piece has no advantages) and prepared and tested in the previously described manner, is placed into one of the tested dialyzers. One and a half c.c. of the pure, clear serum is added to it. In another dialyzer the same amount of serum is placed, but without placental tissue; in a third placental tissue in distilled water without serum. Each of the three dialyzers is then placed in a suitable vessel, such as a large test tube or cylinder, containing 10 to 20 c.c. of distilled water. Both liquids, inside and outside of the dialyzers of each test, are then covered with toluol corked and placed in an incubator for from sixteen to twenty-four hours. To 5 c.c. of the dialyzate from each of the three test tubes 0.2 c.c. of ninhydrin solution is then added and placed in a water bath to boil for from five to ten minutes. After half an hour's cooling the three test tubes are compared as to color. Tube No. 3 must remain colorless; tube No. 2 may be colored violet, while tube No. 1 may approximate in color to that of No. 2 or may be more strongly colored. If No. 1 and No. 2 are of approximately the same color the reaction must be considered negative as to pregnancy. If No. 1 is distinctly more colored than No. 2 the reaction may be considered positive as to pregnancy. The differences in color must be sufficiently marked to be considered conclusive: that of No. 1 should be at least one and a half times as strongly colored as No. 2. This may be determined when an endeavor to equalize the two fluids as to color is made. It should be necessary to add at least one-half c.c. of distilled water to each c.c. of fluid No. 1 to equalize its color to No. 2. For further accuracy, owing to the variability in the rapidity with which different dialyzers permit the diffusion of dialyzable substances, the setting up of double tests and double controls for comparison is to be recommended.

In conclusion, reviewing our results and comparing them with those obtained by the majority of investigators, we find that the Abderhalden test is perfectly reliable and commendable. Schlimpert and Hendry in their last group of 79 cases obtained perfect results, Henkel in 40 cases reports perfect results, Abderhalden's 200 cases, only one discrepancy, McCord's 240 tests with practically no failure, and a number of such other reports certify as to the value, reliability, and utility of the test, provided the latter is performed by competent workers and strictly in accordance with prescribed rules. That the test is of inestimable value in pregnancy (especially in its differential diagnosis) has now been fairly well established, but its usefulness is not limited to pregnancy. Indeed, the field of usefulness of this serological method of diagnosis seems at present exceptionally promising. Ferments seem to be the active agencies in the destruction of tissues in a great number of diseases, such as carcinoma, fevers, eclampsia, diseases with exudates, with parenchymatous degenerations, etc., and low dialyzable proteids have already been found in the sera of those affected with these disturbances. This fact has already been utilized by some of the workers mentioned previously in the diagnosis of nephritis, myxedema, Basedow's disease, syphilis, etc. Epstein reports most interesting results of his experiences by means of the Abderhalden serological test in the diagnosis of carcinoma, citing perfect findings in a considerable number of cases.

To a certain extent the test is objectionable because somewhat complicated and attended with some difficulties, its performance being therefore necessarily limited to special laboratories. The simplification of the test is desirable, so that it can be placed within reach of every practitioner. We have begun an attempt toward such simplification. We have so far succeeded in making from placental tissue an active and durable extract, which will be

enclosed in specially shaped dialyzers, and the rest of the procedure so modified as not to require special qualifications on the part of its performer. As we have not as yet sufficiently completed our experimentations, we must postpone its announcement until a later date.

Cardiac Disease in Childhood.—P. Nobécourt states that in general the cardiovascular troubles are less serious in children than in adults, for the heart of the former has not yet been subjected to the action of alcohol, of various diathetic disorders, or of multiple infections. It is not uncommon to see a child recover from a serious heart affection.—*Journal de Medécine de Paris.*

THE BOWEL DOORMAKER: WITH DESCRIPTION OF TECHNIQUE OF OPERATION FOR SHORT-CIRCUITING BOWEL.*

By ROBERT T. MORRIS, M.D.,

NEW YORK.

PROFESSOR OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL

The doormaker is an instrument for saving time, avoiding hemorrhage, and lessening the degree of peritoneal soiling in an operation for short-circuiting the bowel. The instrument is 12 inches in length, carrying one blade, which is fenestrated, and another blade in the form of a blunt wedge which fits into the fenestrum (Fenestrum 2½ inches long). The blades are bent away from the long axis of the shank at an angle of thirty degrees, for the purpose of avoiding pressure upon the sacral promontory.

When used for short-circuiting the bowel this instrument is passed into the rectum after wrapping the handle in a temporary sleeve of gauze or rubber dam. The object of the sleeve is to prevent the bowel mucosa from slipping between the shafts of the handle and becoming pinched accidentally.

When the doormaker is in the rectum, a customary opening is then made in the midline of the abdomen, just above the pubes, for purposes of bowel manipulation. The distal part of the ileum and the distal part of the sigmoid colon are brought into the abdominal incision together, the doormaker is pushed gently up to this point by an assistant and is then opened. The fenestrated blade remains in the rectum or distal part of the sigmoid bowel, while the wedge blade is passed through a puncture in this part of the colon and also through a corresponding puncture in the wall of the ileum. The jaws of the instrument are then snapped together and held together by an ordinary locking device on the handle. (Instrument made by W. F. Ford.)

A narrow strip of wall of ileum and of wall of colon are deprived of blood supply when wedged into the fenestrated blade by the wedge blade. A few Lembert sutures, at points where they are seen to be needed, will suffice to prevent leakage from the punctures in the walls of the ileum and colon.

The next step consists in angulating the ileum at a point situated near to but distally from the doormaker, for the purpose of turning contents of the ileum toward the door subsequently. Sutures are introduced for the purpose of making this angulation permanent. The sigmoid colon is angulated at a point situated near to and proximally from the

*Presented before the New York Surgical Society, May 14, 1913.

doormaker, for the purpose of preventing antiperistalsis from carrying rectal contents back into the colon subsequently. Sutures are introduced for the purpose of making this angulation of the sigmoid permanent like that of the ileum. The abdominal incision is closed.

Neither the ileum nor the sigmoid colon are angulated to the point of causing obstruction. If reversed peristalsis is excited by the angulation—before the door has become opened—it can be quieted by the employment of opium.

At the end of forty-eight hours the handle of the instrument, which protrudes from the rectum, is pulled upon gently to determine if the wedge jaw has cut its way through the bowel walls. When it has done this the instrument is removed, the door having then been completed between ileum and colon by saprophytic or digestive destruction of the tissue which was wedged into the fenestrum and deprived of its blood supply.

Patients will complain about the presence of the instrument in the rectum, but this complaint is less than the complaint about general distress after the more severe operative work of the Lane operation.

After the door has been made there will be many bowel movements daily for a while, because of the comparatively small new storage room of the rectum, and because the rectum is not accustomed to receiving contents directly from the ileum. Patients will complain about the frequent bowel movements. Starch enemata soothe irritated rectal mucosa, and bowel movements after a while drop down to one, two, or three daily—varying with different patients.

The doormaker was developed for the purpose of simplifying technique and lessening the complications which go with short-circuiting operations. Physicians are apt to be frightened at the idea of the more severe operation when it is proposed for relieving patients with such cases of neuralgia, neuritis, rheumatism, mucous colitis, psychoses, and other toxic demonstrations as are due to colonic stasis.

I would not propose the employment of surgery in any of these cases until medical resources have been thoroughly and well tried out, but when the proper time really comes for relieving chronic constipation by a short-circuiting bowel operation, and for throwing most of the colon with its toxic contents out of commission, the simplest procedure that we can employ for the purpose will be the most desirable. The method which has been described appears to present a simplification of the short-circuiting operation. If further experience brings out undesirable features of the method in theory or application, a report will be made upon all such features later.

MENTAL MORBIDITIES OF THE CONJUGAL STATE.

By THEODORE H. KELLOGG, M.D., LL.D.,

RIVERDALE-ON-HUDSON, NEW YORK CITY.

Mental morbidities of the conjugal state are not alone of practical psychiatric interest, but are nearly allied to subjects which have of late attracted much general public attention and led to special legislation in some of the States. Thus the call for uniform divorce laws, the refusal by some ministers and churches to sanction the marriage of divorced parties, the requirements of certificates of physical fitness of those about to enter the conjugal state, the sterilization of those not to be allowed to propagate, and the whole question of eugenics, all show the active concern of the people in whatever has to do with married life and the family as the basic material of which the whole fabric of society and the nation is builded.

It is therefore the practical importance and the timely nature of the subject which leads to this clinical analysis of the causes and symptoms of the incipient or fully developed psychopathic states which make wreck of family life and often culminate in divorce, suicide, or homicide.

These mental morbidities of the conjugal state have never been adequately studied or described. In their incipient state the family physician often mistakes them for mere exaggerations of the intimate perplexities and personal difficulties which may arise between husband and wife, and finally, when as fully developed cases they are sent to hospitals for the insane, they are set down as due to family troubles or domestic worry. It is plain to the mental expert that frequent divorce court revelations of most outrageous conduct and almost incredible refinements of personal cruelty are often simply authentic instances of the outcome of these psychopathic states. It is a significant fact that the percentage of divorces to marriages in this country is greater than in any other, as shown by actual statistical returns, and that it is constantly on the increase.

The quickest and surest way to a complete understanding of these cases is an analysis of the exciting causes, and attention is invited to this brief practical review of the chief etiological factors. In the first place, when two people enter the conjugal state, which is the closest relationship and partnership possible between two human beings, there is a personal understanding and adjustment to be completely made if the union is to be perfect. If this adjustment is only partial, married life will be compromised, and if there is failure of this personal adaptation there will be at the best only an agreement to disagree, and, at worst, a prolonged open conflict which will likely end disastrously as regards the mental state of one of the parties. The causes which prevent this perfect adjustment in domestic life are various and complex. Differences of age, of social station, of religion, or of race may prove serious, as well as dissimilarity of native characteristics, and what, in common parlance, is known as incompatibility of temperament, for unlike tastes, views, and objects in life are a bar to mental harmony. Likewise, marriages of convenience, without love, for money or social position, especially where affection is already centered in some other person, are wont in the long run to end in mental morbidities.

In this analysis of causes it is clear that whatever occasions prolonged emotional stress may result in these psychopathic states. Thus all the trials or sorrows of married life are to be accorded due weight, such as accidents, sickness or death of husband, wife, or children; the constant cares of rearing, education, discipline, and choice of callings of children, and the lasting disgrace they bring when they turn out bad. Even the economic problems of domestic life demand consideration, for among the poor the constant appeals of children to parents for needed food or clothing which cannot be furnished are highly distressing, and have driven some to crime and others to insanity. Especially keen on

this score is the anxiety of the father as the natural provider for the family, and the sight of starving children is cause enough for a frenzied mental state.

There is a general underestimate of the prolonged mental strain of women in the conjugal state, apart from their admittedly exhausting and great natural function in the reproduction of the species. There is a continuity and multiplicity of everyday doings falling to the lot of the woman who is at one and the same time mother and nurse of children, chief executive of household affairs, directing servants and purveying supplies of food and clothing, and charged with the disbursement of a large part of the family income, and leader in all social functions, to say nothing of her presumed duties as connubial companion. Without a careful study of this host of petty but constant influences it is not easy to understand the resulting nervous exhaustion and mental perturbations.

In this necessarily brief survey of exciting and contributing causes only summary mention is here made of the sexual relations in these cases, even though in the modern deluge of Freudian ideas the sexual thing is the central pivotal point of departure of dreams past and actual morbid mental complexes present. To speak the plain truth in a word, sexual impotence and disease and various sexual perversions may be causative of conjugal misery and of the psychopathic states here considered.

The study of the symptomatology of these cases is next in order, and is facilitated by a division into clinical groups termed the jealous type, the querulous type, and the violent, suicidal, or homicidal type. This clinical grouping of symptoms often holds good throughout the entire mental malady, while in other cases there is some blending of these types.

First, then, as to the jealous type, which is about equally frequent in males and females, and displays in both the same morbid extremes and absurdities of conduct. The husband suffering from this mental morbidity watches the letters and visitors of his wife, and narrows her personal freedom, and after some silly, unsuccessful detective efforts hires professional spies to dog her footsteps, and his early expressions of suspicion soon reach the grade of open reproach and accusations of infidelity. The lack of positive proofs which might narrow or confine the dominant idea only lends freedom to the morbid fancy which runs wild riot and day and night racks the brain of the sufferer. In one of these cases observed by the writer a man of some means and lucky enough to escape confinement as a lunatic doubted the legitimacy of his own son, who strongly resembled him, and disinherited him under this delusion. This man had always been temperate and was successful in business.

As there is no loathing like love turned to hate, some husbands in this group of cases for long periods of time inflict indignities and cruelties on their wives, or their mental disorder may culminate in legal action or personal violence directed against imaginary trespassers on their conjugal rights.

A clergyman in full charge of a parish, preaching good sermons and acceptable in his parochial duties, became a victim of this type of mental morbidity, and confided his jealous suspicions to the wardens of his church. The mother of his wife, being a woman of means and influence in the community, concluded that her daughter's reputation for virtue was more important than the man's reputation for sanity, and had the reverend gentleman consigned to the writer's care for treatment. Thorough investigation revealed no proofs of the wife's frailty or of the man's insanity, apart from his unreasonable and unalterable attitude of jealousy. The matter was settled by a voluntary separation of the conjugal pair, and finally a return of the clergyman to his vocation in another locality.

The wife with this type of psychic trouble secretly watches her husband's callers and his letters, ransacks his closets and his pockets for proofs of her suspicions, which she finds in trifles light as air. Servants, near relatives, and even her own sisters, may become objects of her morbid jealousy. In the meantime she may break out in open accusations of her husband, with display of strong dislike, or may go to the other extreme and make exaggerated demands for his company and sympathy. In fact, these antithetical emotional moods are rather characteristic in the female types of this morbidity. In one of these cases, about whom the writer was consulted, the wife kept her husband, a well-known physician, under espionage for a long time, both as to his office calls and house calls, and as she repeatedly sought women consolers, who in turn became informers, the innocent husband suffered both personal annoyance and professional detriment.

The querulous type now to be described is a mental morbidity of the conjugal state more frequent in women than men. The wife in the incipient stage makes merry at the expense of the husband, and later her jokes are in a sarcastic vein, and finally take the form of open criticism. She chides her children much for slight cause, and later scolds them continuously, and all members of the household come in for their share of gibes. As the malady matures the wife develops a genuine "cacoethes carpendi," a perfect mania for fault-finding, and poses her husband in the light of responsible party to be blamed. He comes to fill her whole mental horizon, and to be regarded as the sole cause of every untoward event in domestic or social affairs. She distorts his remarks into some invidious secondary meaning reflecting upon herself. She comes to mingle self pity with her fault-finding—declares she is a household drudge, grossly overestimating the duties she really performs, and completely failing to appreciate the comforts and luxuries she actually enjoys.

She may speak enviously of wealthy neighbors, and claim if her husband had more affection and enterprise she, too, might have similar enjoyments in life. The querulous mood may eventually blend with an accusatory spirit which charges against the husband, first, personal indifference, then wilful neglect, and finally heartless treatment or actual cruelties. In some prolonged cases there is a remarkable renewal of various characteristics of immaturity—a positive reversion to childish ways, thoughts, and feelings, with loss of womanly, motherly, and wifely efficiencies. There is also a revival of the mother's influence, a desire to return to the mother's home and need of her care and advice. In this connection the patient regretfully compares her former happy lot in her mother's home with her present hardships in the conjugal state.

The husband of this morbid, querulous type begins by finding fault with his meals, criticises the way in which his wife and children are dressed, and ridicules the management of the household in general. He nags his wife first in a jocose and then in an irritable manner, and finally becomes an inveterate scolder. He displays a constant tendency for

argument, and discusses at length the most petty affairs, and during this diseased indulgence in verbal contention does not listen to replies, but continues on in a declamatory and domineering sort of monologue. In this querulous state if personal opposition is made the result is open conflict and constant domestic quarrels, from which relief is often sought in divorce courts, or this open scandal may be avoided if the family physician is sufficiently expert to recognize the mental trouble and separate the parties in time for the recovery of health.

There remains to be noticed the violent, suicidal, and homicidal type, which marks in the conjugal state the possible transition from the height of love and happiness to the depth of despair and cruelty. There is in marriage indissoluble union for weal or woe, and more continuous and profound action and reaction of the emotions than exists in any other relation in life. Mental fibers have their tensile strength and their breaking point, and when the conjugal state brings great and prolonged emotional strain, mental disorder may be expected. There are usually a gradual lessening of inhibitions, loss of self-control, outbreaks of temper, and signs of demoralization before violent acts are committed, but exceptionally all outward manifestations of the extreme inward tension are repressed, and the final suicide or homicide comes like a thunderbolt out of a clear sky. Almost every day the newspapers record these domestic tragedies, which are in a large percentage of cases due to these mental morbidities of the conjugal state. The wife, convinced of the infidelity of her husband, takes the life of her children before she commits suicide, that the whole family may be saved from disgrace. The husband who feels sure of his wife's dishonor kills the imaginary seducer and his life companion, and possibly himself. In rare instances the unhappy pair, having made a wreck of married life, enter into a suicidal pact, and may add child murder to fill up the full measure of horrors.

In fine, it is safe to affirm that the family circle for the husband and wife is the one intimate personal world of worlds, containing all that is nearest and dearest on earth, and when invaded by the demon of discord there is an end of all bright hopes and aims in life. When the domestic "lares and penates" have been broken on the family hearthstone and in their stead has been installed the green-eyed monster, jealousy, peace and love are supplanted by discord and hatred, and there is then no other conceivable environment more highly provocative of suicidal or homicidal acts, or of positive mental disorder.

Out of ten thousand cases of mental disorder which have been under the writer's care and treatment, about two per cent. might fairly be classed as mental morbidities of the conjugal state.

In conclusion there remains to be mentioned the means of prevention of this class of mental troubles. Wise foresight, expert knowledge, and general measures of prophylaxis as broad as the trouble is deep will alone avail. In the first place there should be a thorough educational fitting of young women for the rôle of housekeeping and homemakers. A man at the head of a business which he has not learned is doomed to failure, and much mental strain and endless troubles are in store for the young woman at the head of a household without knowledge of domestic economy, of the culinary art, of the purchase of supplies, or of the practical duties of servants.

The servant problem in this country is in a disgraceful state and is the bane of domestic life, and has caused the mental breakdown of many housewives. The State should concern itself with this matter and establish schools and issue certificates of graduation to those fitted for domestic service.

Young men should be taught something of the mental, moral, and physical nature of women, of the ethics of marriage, and be well instructed in the reciprocal relations and mutual responsibilities of husband and wife and of parents and children. In married life there should never be allowed any ground for friction on the score of conflicting business interests. Ante-nuptial adjustments of money matters are often a wise measure, and the wife is entitled to a perfect understanding of the amount of the annual income to be expended in household disbursements and for her own personal allowance.

The strictly medical measures to be employed vary with the individual nature of the case. There is urgent need of the early advice of a mental expert, who is to sit in judgment on all the circumstances and evidence and prescribe the proper remedial course to be pursued.

In women there is generally indicated relief from care of house and children, change of scene and surroundings, complete rest or outdoor life, and diversions according to the exact physical state, and the cheering company of some young person of her own sex. In men, if feasible, it is best to have respite from business cares, outdoor sports with a genial companion, travel in occasional cases, and sometimes an entire change to a less strenuous occupation. Unfortunately, the financial necessities of the case cause a compromise often between what is absolutely best and what is practicable. In nearly all cases prompt separation of the married parties is advisable for a few weeks, and, in most instances, may be prolonged for some months to advantage.

The whole trend of modern medical science is towards the prevention of disease, and the prophylaxis of the mental morbidities of the conjugal state is only to be accomplished by such broad measures as are here indicated.

AN UNUSUAL CASE OF RENAL HEMATURIA.

UNILATERAL CHRONIC HEMORRHAGIC NEPHRITIS; DECAPSULATION; APPARENT CURE; RECURRENCE; BILATERAL INVOLVEMENT; DECAPSULATION OF BOTH KIDNEYS SIX YEARS LATER.

By WESLEY GROVE VINCENT, M.D.,

NEW YORK

INSTRUCTOR IN SURGERY, NEW YORK POST GRADUATE MEDICAL SCHOOL AND HOSPITAL.

A very careful examination of the literature has failed to show any previous case of unilateral chronic hemorrhagic nephritis which had been treated by decapsulation, consequently the full report of the following case, already previously referred to by me ("The Main Points in the Clinical History and Diagnosis of Renal Congestion," etc., *New York Medical Journal*, April 13, 1907) may be of interest.

On March 28, 1905, Dr. H. C. Pitts of Providence, R. I., referred to me Mr. F. G., age 37, broker, who complained of progressive weakness, loss of flesh, and anemia, due to persistent hematuria. The history obtained at that time was as follows. Father died of Bright's disease, compli-

cated by diabetes. Mother alive, rheumatic and of very nervous temperament. Several brothers and sisters are alive and well except for occasional rheumatic manifestations. No cancer or tuberculosis in the family. Personal history: Measles and chickenpox were the only diseases of childhood. Had severe attack of malaria, tertian type, in 1899, while camping in the South; the chills were very severe and the attack lasted several weeks before any quinine could be obtained, after which time it was quickly controlled. Since then has often been in places where others had malaria, but has never had a second attack. Present history: Two months ago, while on a pleasure trip to England, he noticed that the urine had a reddish color. This soon became so red as to make him feel certain that it was due to blood. Some days the hemorrhage was very severe, and he soon consulted a prominent London physician. A diagnosis was made of renal hematuria, probably due to renal calculus, though there had been no severe pains or other symptoms referable to one kidney rather than the other, and in fact there had been more discomfort over the bladder than in the loins. He did not improve under medical treatment, became discouraged and returned to this country.

Upon his first visit at my office he was very weak from loss of blood, as the hemorrhage had been constant and especially severe during the previous two weeks. I advised complete rest in bed, with adrenalin chloride, ten drops every four hours. However, he had an important engagement in Chicago two days later, and insisted upon taking the train the next morning. When I saw him again five days later the difference in his appearance was very marked. He was very pale and anemic and so weak that he was hardly able to walk across his bedroom. Even the morning urine at this time was port-wine color, and a heavy red sediment was quickly deposited, which microscopical examination showed to consist of myriads of red blood cells. Cystocopic examination showed that the bladder was normal. By ureteral catheterization specimens of urine were obtained from each kidney. That from the left kidney was pronounced by Dr. H. T. Brooks to be practically normal, while the urine from the right kidney was loaded with red blood cells, and there were also many large epithelioid cells and a few casts, principally hyaline. These findings caused Dr. Brooks to make a tentative diagnosis of hypernephroma of the right kidney, although he also suggested the possibility of unilateral chronic hemorrhagic nephritis.

On April 17, 1905, I cut down upon the right kidney. The incision was made along the outer border of the erector spinae muscle, and carried down in the usual manner until the kidney was exposed. All perinephritic tissues were found to be normal. The kidney was large, about 5½ inches in long diameter, and of about normal consistency. The kidney, upper part of ureter, and surrounding structures were carefully palpated and nothing abnormal was found to account for the hematuria except chronic hemorrhagic nephritis. Consequently, it seemed best not to remove the kidney, but to decapsulate, and this was done. The capsule was thin and about normally adherent. As the capsule was removed the kidney parenchyma showed a somewhat yellowish mottling. A small wedge of kidney tissue was removed for histological examination. The wound was closed without drainage; primary union was obtained; convalescence was uneventful, and the patient was back in Wall Street just four weeks after operation. Dr. Brooks' report on the excised portion of kidney tissue was as follows:

"Microscopic examination of fragment of tissue taken from kidney of F. G. showed only that portion belonging to the peripheral part of the cortex. The convoluted tubules, glomeruli, and capsular spaces and, to a minor degree, also the broad (ascending) tubes of Henle, appear to be the portions involved. The lining epithelia of nearly all the convoluted tubules show marked granular degeneration and disintegration, and many of them have also desquamated. Some of the tubules are partly or entirely filled with only granular detritus and desquamated necrotic epithelia, but the lumina of the majority of them are more or less completely occluded by variable admixtures of diffusely distributed granular detritus, and red blood corpuscle shadows embedded in a homogeneous hyaline substance. A considerable number of tubules are filled with more or less densely arranged masses of desquamated necrotic epithelia, red blood corpuscles, and leucocytes embedded in a finely granular basement substance, while a few are obstructed with decolorized and partly disintegrated red cells (intratubular hemorrhage). Here and there a coarsely granular cylindrical mass, in which the faint contour of cellular elements can still be made out, are seen occluding the lumen (casts). The glomeruli are in some places swollen, and the capillaries widely dilated and empty; in other places they are compressed by an exudate into the capsular space of Bowman. This exudate in the capsular space varies in composition from pure blood or granulohyaline material to variable admixtures of desquamated capsule cells, leucocytes, red blood corpuscles, and granular and hyaline basement substance. The capsule itself is slightly thickened, loosely reticulated; the nuclei apparently slightly increased in number, but otherwise unaltered. A number of the broad tubes of Henle are filled with coagulated hyaline, coarsely granular and cellular masses (casts), but the epithelial lining is but little affected. The interstitial tissue is here and there loosely fibrillated, and the larger or smaller spaces thus formed are filled with a translucent coagulated hyaline material (edema). Other small areas are infiltrated with numerous polynucleated leucocytes in addition to the edematous infiltration. Rarely a small focus of fibrosis was observed."

At the time of operation, blood had been present in sufficient quantity to color the urine a light or dark port-wine color for nearly three months, while the patient had become so weak from loss of blood that he could hardly walk across the room. *Six days after decapsulation the blood disappeared from the urine macroscopically,* though it was about three months later before a specimen was obtained in which the microscope failed to show any red blood cells. The patient regained health and strength rapidly after leaving the sanatorium, and gradually returned to normal condition, though the microscope occasionally showed a few isolated red blood cells. Numerous urine examinations were made, of which the following show the course of the case: March 28, 1905 (about three weeks before operation). Sp. g. 1023; albumin, 25 per cent. by bulk; 1/10 of 1 per cent. quantitatively; no sugar; urea. 2.5 per cent. Few hyaline and blood casts; myriads of red blood cells (typical findings in specimens before operation). May 13, 1905 (26 days after opera-

tion). Quantity, 1000 cc.; sp. g. 1025; albumin, very faint trace; no sugar; urea, 2.9 per cent.; rather frequent hyaline casts; occasional epitheliated and partially finely granular casts; numerous mucous cylindroids; occasional isolated red cells; calcium oxalate crystals. October 2, 1905 (about six months after operation). Sp. g. 1034; no albumin; no sugar; marked indican reaction; occasional hyaline cast; innumerable mucous threads and cylindroids; very rarely an isolated red blood cell; innumerable calcium oxalate crystals. February 11, 1907 (nearly 2 years after operation). Quantity, 1500 cc.; sp. g. 1024; no albumin; no sugar, urea, 2.3 per cent.; indican, trace; very rarely a hyaline cast; numerous mucous threads and cylindroids; very rarely an isolated red cell; few calcium oxalate crystals. December 18, 1908 (3 years and 8 months after operation). Quantity, 1800 cc.; sp. g. 1018; no albumin; no sugar; urea, 1.7 per cent.; rarely a hyaline cast; occasional mucous shreds; no blood; no crystals.

About three weeks before this specimen was passed the urine had a reddish tinge for two or three days. This slight hemorrhage was the first sufficiently large in amount to color the urine since the operation, over three and a half years previously. After this time slight hemorrhages occurred at very irregular intervals (weeks to months apart), the first rather severe attack coming in April, 1910. The urine report for April 18, 1910 (5 years after operation), showed sp. g. 1018; marked trace albumin; no sugar; urea, 2.2 per cent. Very rarely a hyaline cast; occasional blood cast, and large amount red blood cells, singly and in small masses.

At this time he weighed 200 pounds, his general health was good, and, except for a temporary neurotic condition, due to overwork and the occasional hemorrhages, he considered himself well. Cystoscopy, to determine whether the hemorrhage came from the decapsulated or undecapsulated kidney, was suggested at this time and declined. In July, 1910, the hemorrhages began to appear more frequently, and by fall clear urine was the exception and bloody urine the rule, though even the worst hemorrhages at that time were not as severe as those in 1905. Gradually, however, the hemorrhage increased in severity and became practically constant by spring, 1911, the urine reports approximating that of March 28, 1905, quoted above. Moderate muscular weakness developed upon comparatively slight exertion; his mental processes became somewhat sluggish and memory tricky, and as medication had absolutely no effect on the bleeding he requested me to operate again and to decapsulate one or both kidneys, as I deemed best.

Accordingly, on April 22, 1911, he was prepared for operation. After he was anesthetized I cystoscoped, and found that the hemorrhage came from both kidneys. He was then placed prone on my special two-compartment triangular kidney cushion, and both kidneys were decapsulated. Edebohls' technique was followed throughout, except in the substitution of my own for Edebohls' kidney cushion. The left kidney was enlarged, measuring full 5½ inches in the long diameter. The capsule was thin, and about normally adherent, while the parenchyma showed the yellowish mottling, as noted at the original operation on the right kidney, six years previously. The right kidney was more firm to touch, and was appreciably smaller, the long diameter being about 4½ inches. The capsule was rather thick and adherent. In a number of instances minute wedges of parenchyma came away with the capsule, while the raw surface of the cortex as a whole appeared somewhat granular. A number of small vessels passed from the perinephritic tissues into various portions of the capsule where they were lost, while two rather large vessels penetrated the capsule near the center of the convex border, giving considerable hemorrhage when the capsule was stripped from the cortex. Small wedges of parenchyma were excised from each kidney for histological examination, while the generous portion of the right (reformed) capsule was preserved for the same purpose. Dr. Brooks reported that the pathological condition found in the left kidney was precisely similar to that noted in the right kidney six years previously and reported in detail above. The second specimen from the right kidney showed typical "replacement fibrosis," namely, areas of parenchymatous degeneration, with substitution of fibrous tissue in these locations as well as an increase in the connective tissue stroma generally. Numerous small wedge-shaped fibrous areas were seen running down into the cortex, the retraction of these accounting for the somewhat granular appearance noted at operation. The portion of reformed capsule showed nothing but a very richly vascular connective tissue membrane, with here and there fragments of cortex which had been torn off as the capsule was stripped away.

Unfortunately, the dressings were accidentally soiled, and both wounds were infected externally by the colon bacillus, necessitating reopening of the superficial tissues, the deep sutures not having to be disturbed. The infection was soon controlled by swabbing with 95 per cent. carbolic acid, followed by 95 per cent. alcohol and wet dressings of 1-1000 bichloride, and the patient left the hospital at the end of the regulation four weeks.

The course since this second operation has been very disappointing. There has never been a time when the urine has been free from blood microscopically, and seldom when there has not been enough to give it a decided pinkish tinge. As a rule it has been frankly red, with copious red sediment and a marked reaction for albumin. This was the urine condition at the time of last report in July, 1912. His general health has, however, improved, and he has been leading a rather strenuous life recently on a large ranch in the West.

CASTRATION AND OPERATIONS FOR VARICOCELE AND HYDROCELE WITHOUT WOUNDING THE SCROTUM.

By CHARLES AUBREY BUCKLIN, M.A., M.D.

GLASGOW, SCOTLAND.

Operations have been performed for thirty years by the author in the treatment of these diseases by a longitudinal incision through the anterior wall of the scrotum. There have been frequent failures because some of the necessary details regarding the pathological conditions were overlooked and in consequence the required treatment was not carried out. The primary cause of failure was that the incision through the anterior surface of the scrotum did not expose the diseased tissue sufficiently to enable the operator to examine it thoroughly.

In castration, tubercle deposits which are the

most frequent causes for these operations, and neoplasms and neoplastic infiltrations, the presence of which also necessitates these operations, were not discovered in the tissues operated upon because the incision made through the anterior scrotal wall did not expose them to the operator sufficiently to make these defects visible. In varicocele one is unable to tie off the vein sufficiently with an anterior scrotal incision, so that when their ends are joined they do not lift the testicle to the proper height to produce in every case a cure of this disease. In hydrocele one is less frequently able through the scrotal incision to close to a sufficient extent and tightly enough the physiological covering of the testicle, the tunica vaginalis propria, to insure a cure of this disease.

In castration by the inguinal method a transverse incision is carried downwards and inwards over the canal a finger's breadth above and parallel to the inner half of Poupart's ligament.* This inguinal incision gives an extensive view of the parts operated upon, it enables the operator to follow the vas deferens down to its entrance into the prostate gland, in tuberculous and malignant diseases thus making the cures more satisfactory. This wound heals much more promptly and more firmly than the scrotal incision, and it is for the reasons given much more popular with the operators who have used it in treating these diseases. They are usually able to complete operations with success and without complications through the inguinal incision which could not have been accomplished with the anterior scrotal incision. This incision corresponds exactly to the line of cleavage of the skin and therefore it comes together very easily.

Two large veins which descend in the superficial fascia, one at the outer and one at the inner part of the wound, require to be ligated. When the incision is prolonged outwards the superficial epigastric vessels are divided. The external spermatic facia, which is prolonged down upon the cord from the edges of the external abdominal ring is then divided; next, the muscular fibers of the cremaster, from the internal oblique; and the strong infundibuliform fascia, the continuation of the fascia transversalis, are similarly divided. Within the extension of this fascia, enclosed in the tunica vaginalis propria, lies the round ligament in the female and the spermatic cord in the male which is occasionally attacked with hydrocele. It consists of an infusion of fluid under the tunica vaginalis propria and frequently associated therewith is also a peritoneal diverticulum in the form of a hernial sac. In castration the testicle is pulled upwards, the vas deferens is cut through, and the spermatic artery, the artery to the vas deferens, and the venous plexus are individually caught up, ligated, and divided. When this must be done higher up on account of the presence of tubercle deposits or infiltrated nodules from malignant disease deposited in the vas deferens, the anterior wall of the inguinal canal, the aponeurosis of the external oblique, must be slit up. Should the disease extend still deeper subperitoneally, the postrior wall of the canal must be slit up and the canal carefully sutured thereafter.

Provided the testicle is not adherent to the scrotum, or decidedly enlarged, it may be easily pushed upwards out of the wound and removed. When the skin is adherent, or the tumor of the testicle is very large, castration is performed by means of a transverse incision in the coronal plane at the lower end of the scrotum. After division of the skin and dartos between the larger visible scrotal vessels the testicle is shelled out. As the incision is parallel to the scrotal vessels, and also parallel to the branches of the spermatic vessels which ramify upon the surface of the tunica vaginalis toward its lower pole, it is a much more suitable incision than that which is generally used in Great Britain and America. Here a vertical incision descending upon the anterior wall of the scrotum is the general incision used.

Castration is the correct operation for all malignant growths, but there is a difference of opinion regarding its use in tuberculosis of the testicles. Baumgarten's remarkable researches read before the thirtieth congress of the Society of German Surgeons, 1901, show that tuberculous infections can only take place from the testicles upwards and never take place from the prostate downwards. The author is personally in favor of attempting to cure the tuberculous developments in the testicles by the administration of one tumblerful of pure, sterilized milk every thirty-six minutes to a male patient for twelve hours, which is followed upon retiring for the night by a sufficient dose of fresh castor oil in black coffee or beer to insure an open alimentary canal, which is an absolute necessity if this forced feeding is to be tried. This treatment should be carried out for three months before castration is resorted to for the cure of tuberculosis of the testicles. Should the patient show an increase of weight castration will not be required as an antidote for tuberculous disease of the testicles. The author's paper on the "Treatment of Pulmonary Tuberculosis, Diseased Lacrymal Ducts, Catarrhal Otitis Media, Hay Fever, and Chronic Asthma Not Complicating Heart Diseases" is referred to as containing full particulars.*

Cases of varicocele are all permanently cured by the above described operation without complications, owing to the fact that from four to six inches of the vein can be removed from the spermatic cord every time by this operation; the operator is thus enabled to shorten the support to the testicle to the desired length. The author closes all of the wounds, even the external one, by continuous catgut or silk sutures, which are covered when exposed with a small piece of sterilized bandage which is cemented down by collodion applied over it. The necessary piece of vein cannot always be removed through an incision on the anterior wall of the scrotum that is required to cure varicocele. The inguinal incision thoroughly exposes the tissues and also allows one to observe if any possible complication is present. After the ligation and removal of this piece of vein, the ligating sutures are left long and tied together for supporting the testicle in a higher position than its former location. In hydrocele the testicle is greatly indebted to the inguinal incision for its future normal resting place and the uncomplicated nature of the cures by this improved method of operating. These perfect results cannot be regularly attained with the incision on the anterior surface of the scrotum.

The sac can usually be pressed out through the inguinal incision. If very large, by infusion it may

*Although the inguinal incision was described by Kocher in the earliest editions of his textbooks on operative surgery, it has recently been published by Pasquimangali as something new, and it is even referred to in the *Centralbl. f. Chir.*, No. 47, 1906, as something new.

**Journal of Laryngology, Rhinology, and Otology*, September, 1911.

be partially emptied by puncture, when the testicle and its physiological covering is thoroughly exposed through its entire length. This covering, the tunica vaginalis propria, is sufficiently removed to leave just enough of it to cover the testicle tightly throughout its entire length, where it has been formerly separated from this membrane by fluid. The tunica vaginalis propria, which is the normal membrane surrounding the testicle, is closely united by a continuous catgut or silk suture about the testicle, which produces a satisfactory cure of this disease in every case. The testicle thus closely enclosed in its natural covering is returned to the cavity in the tunica vaginalis communis and the opening therein is closed by a continuous suture of catgut or silk. With the incision on the anterior scrotal surface the above described details were very imperfectly completed, because the operator could not see distinctly the pathological defects in consequence of which the diseases frequently returned.

This lack of success with the anterior scrotal incision suggested the only operation which has been generally successful when used in connection with the anterior scrotal incision to be devised. This operation consists in removing the testicle from the tunica vaginalis propria and closing with a continuous suture the opening in this membrane through which the testicle has been removed and then returning the testicle without its natural covering into the cavity formed by the tunica vaginalis communis. The testicle is always surrounded by a foreign membrane which is frequently an annoying disadvantage to the patient. It leaves the testicle subject to chronic irritations, although the tendency of the testicle to swell has entirely disappeared. It is a safe conclusion in surgery not to disturb the physiological surroundings of tissues when an equally good result can be obtained by leaving them in their natural relations. The operations by inguinal incisions which readily allow these diseases to be cured without disturbing the physiological relations of the coverings were devised by Kocher,* and according to his words, which are here quoted, he has always been successful in curing these diseases.

The author's experience has been positively in favor of this inguinal incision in castration and operations for varicocele and hydrocele. Where there is an additional deformity of an enlarged scrotum it can readily be perfected by the removal of a sufficiently large elliptical piece to remove the enlargement, the resulting wound being united by a continuous suture of No. O catgut or silk.†

†These operations can all be performed with local anesthetics consisting of 20 minims of a 10 per cent. solution of novocaine, which is introduced with a hypodermic syringe into the parts requiring this operation. If a general anesthetic is used the author strongly recommends pure ether.

Moraybank, Langside.

Piercing the Ears of Children.—Alois Epstein has made an exhaustive study of this practice, which he finds still widespread among the poorer classes, although it is still prevalent to the extent of 50 per cent. among the upper classes. Among the unsightly results of this operation occasionally noticed are complete clefts through the pinna, openings that have been closed by cicatricial tissue, and large irregular openings, all the result of suppurative complications. Among other untoward results are erysipelas, delayed healing in children of the exudative diathesis, eczema of the lobule, and worst of all tuberculosis of the latter. The author reports two cases of this condition.—*Zeitschrift für Kinderheilkunde.*

HEMORRHOIDS AND OFFICE PRACTICE.

By ERIC CARL BECK, M.D.,

NEW YORK.

ATTENDING SURGEON TO ST. MARK'S HOSPITAL; CHIEF OF SURGICAL O.P.D. GERMAN POLYCLINIC.

Preoccupation and constipation seem to be conducive to hemorrhoids. Floundering about in the maelstrom of bustle and activity of a business life, men and women alike pay but little heed to that most important function of the body, the punctual evacuation of the bowel. Nine women out of ten will tell one that their bowels move all right when they take something and cannot be convinced that a bowel-movement every second or third day is not a natural state of affairs. The usual form of constipation is a sequence to carelessness of personal habits and this carelessness invites and promotes the formation of the succulent hemorrhoid.

In the cities, where thousands are occupied with clerical positions, the hemorrhoidal martyr abounds in large numbers. Physicians practising there are familiar with the type, and when a stranger walks into the office with the perturbed attitude of one balancing an imaginary object on his head the thought flies to the doctor's brain, "Aha, another hemorrhoid."

As a rule, when a patient becomes bothered by an inflamed or congested hemorrhoid, he seeks the nearest physician who promptly and properly advises rest, very light diet, perhaps cold local applications and a suppository containing opium or some other "pain-killer." If the pile is not too large or too much distended, these measures are sufficient to restore the patient to normal within two or three days. This treatment is pleasing to both patient and physician; it is successful and painless. No operation, no cutting, that bugaboo of the laity. But many of the hemorrhoids have gorged themselves, and, satiated with blood, their paunch protrudes into the gateway of the body and then all these measures are for naught. When operation is advised the patients are usually sent post-haste to a hospital or sanatorium where the hemorrhoids are removed *in toto*. The case is turned over to the rectal specialist and this is usually the last the physician sees of his patient.

Before taking up the subject of office-treatment it might not be a waste of time to insert a few remarks concerning the operations advised and devised for the removal and cure of hemorrhoids. In looking over the literature on hemorrhoids I was surprised to note the astounding similarity of the operative procedure as described by three different surgeons. Each one of them espouses the clamp and suture, the only difference being in the kind of clamp used. Two of the gentlemen use the Kocher forceps, while the third has devised a clamp of his own. The first report was published June 1, 1901, the second February 28, 1903, and the third June, 1906. As they are all alike I will quote the essence of the first: "The entire mass is caught and cut off close to the clamp and while the clamp is still holding the base an overstitch of catgut is inserted and fixed as the clamp is removed, thus burying the stump. There is no danger of hemorrhage, very little pain, a quick recovery, and absolute cure. It also permits the patient to resume his or her vocation in the shortest possible time."

No doubt this operation is an improvement over the old clamp and cautery, in which the overzealous operator has often used the cautery to such good

effect that the anus became almost inverted on itself. But its greatest attraction to the layman lies in the rapidity of repair, in the short time that the patient is kept from his vocation.

Since then an operation has been described by J. M. Lynch in the *Medical Review of Reviews*, October, 1907, which is extremely simple and can be performed in the physician's office. The following is an extract: "The patient is placed in the Sims position, on the right or left, with the knees well flexed, and asked to strain. When the hemorrhoid to be obliterated is selected, a needle, threaded with plain catgut, is now placed beneath the mucosa into the cellular tissue at the base, where the blood-vessels enter, and brought out on the other side, thus embracing both the blood-vessels and a little of the mucosa. The suture is now tied, the loose ends are cut off, and the hemorrhoid is allowed to recede into the rectum. As the base is within the sphincter and outside of the sensitive zone, there is no pain. The same procedure is then followed should there be others to be eliminated. An opium suppository is now inserted to prevent the bowels from moving and to allay the after-pain. The hemorrhoids do not slough off, as one might expect, because only the blood-vessels entering are tied, and the muscoa has sufficient blood-supply to nourish itself without these. The tumors swell for the first 24 hours, but afterwards gradually subside leaving nothing but a hard, bloodless mass of connective tissue. This is also absorbed in time, when the hemorrhoids are obliterated. The advantages of this operation are: (1) It is bloodless. (2) If desirous of hastening the process, the hemorrhoids can be removed without hemorrhage or pain, a few weeks after they are tied, by simply cutting them off with the scissors. (3) It offers a cure to those who refuse a cutting operation. (4) It is simple and can be performed by any one if the proper surgical precautions are observed." I have employed this technique several times in my clinics at St. Mark's Hospital and have found that Lynch's contentions are correct in every detail. However there is usually great pain for from 24 to 48 hours after the blood-vessels have been tied. I have gone further than that and have removed two hemorrhoids without pain, by following the same method but injecting a solution of Beta-eucaine and suprarenal extract before the operation. I use eucaine in all my minor surgery. The injection of the very weak solution caused a dissection of the tissues and an outbulging of the entire mass. I made an incision about half an inch long at the base of the hemorrhoid and ran a catgut ligature around the pedicle. Inserting a grooved director I was able to free the hemorrhoid from the mucosa, there being no adhesions on or around the sides; only a small area at the top. I then incised the hemorrhoidal sac, pressed out the contained blood, passed a hook around the mass, everted the empty pouch and cut it off just above the ligature. I repeated the process on the other side, painted the cut surface with tincture of iodine, inserted an opium suppository and applied a T binder. There was no afterpain to speak off. Simply a feeling of discomfort. When I saw the patient the next day there was slight edema and some discoloration of the mucosa, probably caused by pressure and traction during the operation. I was anxious lest the loose folds of the mucosa slough away, but my fears were groundless as they began to contract shortly after and the end-result was a perfect one. The patient's bowels were kept under control for four days with the aid of bismuth and opium powder.

Operations on hemorrhoids in the office, unless the case is an extreme one, can become the rule rather than the exception.

333 East Sixth Street.

LEPROSY AND THE KNIFE.

By E. S. GOODHUE, A.M., M.D., LL.D.,

HOLUALOA, HAWAII.

In an official publication of the Hawaiian Board of Health, for the twelve months ending June 31, 1912, the medical superintendent of the Molokai Leper Settlement, Dr. W. J. Goodhue, furnishes a report which is of great interest to the scientific and surgical world. Since the present incumbent's residence at the settlement, many changes for the better have taken place, due not only to Dr. Goodhue's suggestions, but to the fine executive ability of Mr. McVeigh, the superintendent, and the ready acquiescence of the Territorial Board of Health. New and commodious buildings have been erected and an adequate surgical and dressing room and modern equipment for the bi-weekly surgical clinics established by the operator have been installed.

These clinics, where contractures, ulcerations, necrosed and mutilated fingers and toes—and, in fact, all the disfigurements due to the ravages of leprosy—are treated, were the conception of the surgeon in charge, who has surgically treated in this place over 6,000 patients. His enthusiasm, perseverance, and skill have overcome all obstacles. Koch, who visited the settlement a few years ago, and many other distinguished physicians and scientists, have spoken highly of the work done there, and expressed their surprise at the results.

The following is taken from the last official report:

"Case I.—P. was declared a leper in 1906 by the Examining Board for lepers, after a careful examination in conjunction with the report of the official bacteriologist. He entered the Leper Settlement, Molokai, October, 1906. He presented extensive ulceration of the inner aspect of the arm, extending above, from a line corresponding with middle of axillary cavity, to the angle of elbow below. Widest ulceration, 4 inches, tapering down to from 1 inch to 1½ inches. Induration was marked, there was difficulty in flexion of forearm, and considerable necrotic involvement of the biceps. Operation was a radical dissection of the tissues involved, followed by 10 per cent. zinc chloride irrigation. Care was taken to arrest circulation by Esmarch's bandages during operation, and these were only removed subsequent to aforesaid and additional antiseptic cleansing.

For conservative reasons I have purposely refrained from reporting this case until a sufficient length of time had elapsed, so as to place the cure beyond the shadow of a doubt, or the possibility of metastatic recurrence. Eight months after the operation, the patient was brought before the official examining board, presented no physical blemishes, and rigid bacteriological tests were neutral. The patient was declared non-leprous, discharged from the settlement, and is now leading a useful life as a road overseer on the Island of Maui.

However unusual the statement may seem to those not clinically familiar with every phase of leprosy, I boldly assert that in the unsuspectedly large number of incipient cases where the disease is localized (peripheral and nerval) these or any other treatments which remove the then circumscribed area or focus of infection, without opening up channels for metastatic dissemination, will cure the disease in from six to twelve months' time. Ferruginous and nutritive tonics, emunctorial eliminants, including

hydrotherapy, are here of more than ordinary importance. While a cure of leprosy is always interesting as well as gratifying, I report this case and would also call attention to Cases II and III (given below).

Class A includes cases which especially emphasize a few points which have been borne in upon me as the result of ten years of uninterrupted clinical observation and the performance of over 6,000 surgical operations for the amelioration of every form of leprous lesion amenable to surgical intervention.

(1) Leprosy is more frequently than otherwise primarily a localized disease. (2) As such it may be eradicated through the judicious application of suitable topical remedies, or careful surgical interference. (3) The whole period between infection and development of the primary lesion (incubation) may be as short as five days.* (4) The initial focus may remain localized for anywhere from a few months to years or even a lifetime, through (a) natural, physiological, and economic phenomena, and (b) artificial circumscription or walling in of the primary infection as in the subcutaneous injection of a five per cent. solution of carbolic acid. (5) Leprous rhinitis or "snuffles" is very infrequently neither a primary infection or manifestation, but usually secondary to general or systemic invasion, and occurring only after a longer or shorter (more commonly the former) period of localization.

Left undisturbed, unrecognized, or untreated, systemic infection and general dissemination of the bacilli may occur from autoinfection through (a) natural proliferation of bacilli and toxins generated; (b) traumatic injuries such as lacerations, contusions, luxations and fractures; (c) intercurrent fevers; (d) intemperance and debauches with the usual concurrent exposure; (e) natural susceptibility or the same acquired through loss of bodytone; (f) and in the female, pregnancy.

"Case II.—A married woman, aged twenty-eight, entered the settlement as a leper, with her husband, in 1908. She presented an extensive eruptive skin affection of the abdomen and part of the left thigh. The eruption took the form of numerous irregular concentric rings separated by patches of healthy skin. She was placed on chaulmoogra oil, and the elixir of iron, quinine, and strychnine phosphates. Locally there were used at intervals tincture of iodine, pyrogallic and salicyclic acid ointments, and sulphur baths. The eruption seemed to be gradually closing in, so that a year ago, when thorium paste was begun, the eruption resembled a large plaque with the rings largely coalescing to form a single patch. This result was due largely to the irritant drugs used and the friction employed to relieve itching rather than to an increased activity in the specific lesions themselves. Application of the paste was made every third day, covering about 2 inches at a time. The day following the application of the paste the patient herself used the ointment. Result: the eruption has about all disappeared, leaving good, clean skin. The internal treatment was changed to Fowler's solution, alternating monthly with Blaud's pills. I hope to present this case for examination at the next meeting of the Examining Board, and I believe the woman will be declared non-leprous.

"Case III.—Mrs. K. H., married, aged twenty-three. No children. Entered settlement in 1904. Presented indurated, discrete patches on face, principally between the eyelids and the cheeks, which were raised, as an eruption, or depressed, the latter appearing like the pitting of smallpox. In every other clinical aspect the case shows absolutely no lesion, sign, or symptom of the disease. To put it differently, the bacilli of Hansen, wholly responsible for the leprosy, are localized in certain circumscribed facial lesions, and the infection, although existing over nine years, has never succeeded in becoming systemic."

The Doctorage

*American Medicine, October, 1907.

THE ADMINISTRATION OF OXYGEN TO THE FETUS.

By GEORGE P. SHEARS, M.D.,

NEW YORK.

ATTENDING OBSTETRICIAN, CITY, POLYCLINIC, AND MISERICORDIA HOSPITALS.

In the Medical Record of January 11, 1913, there appeared a short article of mine upon the treatment of the toxemia of pregnancy. In that article I ventured to advance the theory that suboxidation is the chief factor in the production of preeclamptic toxemia, and that the free use of oxygen, either by inhalation or subcutaneously, is a valuable method of treatment and one which does not interfere with other methods of proved efficiency, such as rest, milk diet, catharsis, hydrotherapeusis, and so on. Further experience, which I hope to report later, has served to confirm my opinion, and I now believe that the occasional administration of oxygen in pregnancy is desirable and beneficial, acting as a prophylactic and invigorator even in cases approximately normal, and especially when the patient is obliged to remain indoors a large part of the time. I also believe that it will do much to relieve subjective weakness, oppression, and discomfort, in cases that are probably mildly toxic, but not far enough advanced to present typical symptoms.

The object of this communication, however, is to call attention to certain immediate effects of oxygen upon the fetus, which have, I think, hitherto escaped attention.

In the first place, the inhalation of oxygen by the mother appears to increase the rapidity of the fetal heart. I have before me the notes of eleven tests made at the City Hospital. Each test consisted in the inhalation of oxygen for five minutes by a pregnant woman at or near term, the fetal heart being counted before and after inhalation. Fetal movements were also observed, and uterine contractions noted. In order to eliminate the personal element I did not do the counting myself, but entrusted the task to one of my assistants. The rapidity of the fetal heart sounds was increased in every case. In two cases the increase was so small as to be practically negligible, two and four beats respectively; in a third it was eight beats, and in the remaining eight cases it was from sixteen to twenty-five beats. The average increase was about fifteen beats. The real increase was somewhat greater than is here indicated, since the inhalation of oxygen appears to excite uterine contractions, and in at least four cases the counting was done during a contraction. It is a matter of everyday experience that the fetal heart beats more slowly during a contraction.

Another new and curious fact noted during these experiments is that oxygen increases the frequency and activity of the fetal movements. Out of nine tests it was found that the fetal movements were increased in five. In three of these they were marked simply "increased" and in the remaining two "markedly increased." In the case of one patient near term and since delivered, the fetus underwent remarkable contortions, but without harm.

Why do the fetal heart sounds become more rapid, and the fetal movements more active, under the influence of oxygen? Certainly not because of a general stimulation of the maternal organism. Drugs given by the mouth or hypodermically do not ordinarily affect the fetal heart. The fetal and maternal circulations, however, are really one, and if oxygen

enters into chemical combination with the maternal blood, how can the blood of the fetus escape its influence?

Now if we can administer oxygen to the fetus, and if the fetus responds symptomatically to that administration, is it not plain that we can do much in the prevention and treatment of antenatal asphyxia? The normal slowing of the fetal heart during contractions ususually does no harm, but if labor is much prolonged or if the contractions become tetanic in character, the fetus will sooner or later show the effect of the diminished supply of oxygen. During a uterine contraction there is of course a corresponding diminution of the placental area. The fetus thus receives less blood and consequently less oxygen. In our experiments at the City Hospital the fetal heart sounds were increased in frequency during the contractions. Therefore it would seem a wise precaution to administer oxygen to the mother in cases of prolonged second stage, in partial separation of the placenta, or whenever slowness or irregularity of the fetal heart sounds indicates impending asphyxia.

I am aware that there are many sources of error in counting the fetal heart, but the fact that in eleven cases an increase was noted in every case, that the average increase was about fifteen beats per minute, and that in some cases it was as high as twenty-five beats per minute, and that in a large proportion of cases the fetal movements were increased, sometimes markedly so, seems to indicate that the inhalation of oxygen by the mother is not without its effect upon the fetus.

I may add that since the above tests were made I have supervised two further tests. In both the heart rate was increased ten beats per minute and fetal movements were observed.

I have also had an opportunity to observe the stimulating effect of oxygen upon the fetus in a difficult version.

203 West One-hundred-and-third Street.

Medicolegal Notes.

Physical Examination of Injured Party—X-Ray Photographs.—In an action against a railroad company for personal injuries, the defendant moved for an *x*-ray examination of the plaintiff, a married woman, and a physician was appointed by the court to make it. The physician proposed to engage a photographer to make *x*-ray photographs, to which the plaintiff objected, and refused to submit to an examination under these circumstances. The Florida statute gives a trial court discretionary power, in a suit for damages for personal injury, to appoint a physician to make a physical examination of an injured party. It was held that the statute be exercised with due regard to the rights of the parties and confined to its expressed terms. A physician appointed by the court for the purposes indicated in the statute must himself make the physical examination; and, while he may use the *x*-ray in his examination, he has no authority to take *x*-ray photographs of the person of the party examined without his or her consent; and much less has he authority to appoint an outside photographer to use the *x*-ray, or to take such photographs.—State v. Call, Florida Supreme Court, 59 So. 789.

Insurance—"Serious Disease or Complaint."—A life policy provided that it should be void if the insured had been attended by a physician for any "serious disease or complaint." Proof was given in an action on the policy that the insured, prior to the application, had malaria, congestion of the kidneys, and endometritis. The trial court found that the insured had not been attended for any serious illness. There being no testimony in the record that any of the diseases named might reasonably entail permanent or material impairment of health, it was held that the finding was not reversible error.—Metropolitan Life Ins. Co. v. Little, Kentucky Court of Appeals, 149 S. W. 998.

Misrepresentation as to Cure—Deceit.—A complaint substantially alleged that the plaintiff was suffering from irritation of his stomach, and applied to the defendant for advice and treatment, which the latter undertook to give. Thereupon the defendant, for the purpose of deceiving the plaintiff, falsely and fraudulently made a pretended diagnosis of his condition, and advised him that he was suffering from rheumatism of the stomach, and that the proper and necessary treatment therefor was to cover a large portion of his body with a plaster, which the plaintiff afterwards learned was composed of olive, amber, and kerosene oils. The defendant also represented as of his own knowledge to the plaintiff that this treatment would have no injurious effect upon his health, but that it would cure the ailments from which he was then suffering. The defendant at the time of making such representations knew each of them to be false, and made them for the purpose of deceiving the plaintiff and inducing him to submit to the treatment and thereby get his money. The plaintiff believed and relied upon the false representations, and submitted to the proposed treatment, which did not cure him, but on the contrary, injured his health and severely blistered his body, causing poisonous sores and ulcers thereon, to his damage in the sum of $10,000.

The trial court sustained a demurrer to the complaint and on appeal the question was: Did the complaint state a cause of action for fraud? It was held that it did, under the rule that, where one deliberately makes a false representation of a material fact, or as of his own knowledge without knowing whether it is true or false, intending that another shall act upon it, and he does so to his injury, an action for deceit lies. It was immaterial that the defendant did not in fact obtain any money from the plaintiff, as the injury to one's person by fraud is quite as serious as injury to his pocketbook.—Flaherty v. Till, Minnesota Supreme Court, 137 N. W. 815.

Insanity of Defendant—Privilege of Family Physician.—In a murder case where the defense was insanity, a medical witness for the State was asked on direct examination whether, in his opinion, the defendant was or was not insane on the day of the murder. In cross-examination at this point by the defendant it appeared that the witness had been the family physician for the defendant's family for several years before. The State then asked him if he could separate his conclusions from his professional calls on the defendant and his observations on the day of the murder. He replied that he could. His answer that he saw nothing to indicate but what the defendant was competent and sane was objected to by the defense, chiefly on the ground that it was a privileged communication Many courts have held such evidence incompetent. It has often been said that the human mind is not competent to separate the facts of which it is cognizant into two classes —those that were obtained professionally, and those coming within the observation of the witness not so obtained—and distinguish an opinion derived from one series of facts from an opinion derived from another. Some have suggested that the witness might not be competent to determine as a matter of law how far the rule of personal privilege extends and so be able to determine what facts the law would regard as having come to him through his professional capacity. Without deciding the point the court held the evidence incompetent because his testimony amounted, not to a statement of what his opinion was as to the sanity or insanity of the defendant, but that he had not observed enough to lead him to the conclusion that the defendant was insane, without testifying to the facts and conditions which he had observed.—Larson v. State, Nebraska Supreme Court, 137 N. W. 894.

Masseur Practising Medicine.—A conviction of a masseur for unlawfully practising medicine was affirmed where the State alleged and proved that the defendant practised upon human beings and treated them for disease and disorder as a doctor or physician and charged indirectly therefor without procuring and having registered a license therefor. The defendant claimed that he did not so practise, but that he practised simply and solely as a masseur.

Masseurs in their particular sphere of labor, it was held, who publicly represent themselves as such are exempt from the law requiring a certificate of their authority to be recorded before practising that art, but if, notwithstanding he so represents himself as a masseur, he undertakes to cure diseases for pay, and represents himself as able to cure diseases in that manner, he could not do so legally without the proper certificate registered in the clerk's office, etc. In other words, he could not hold himself out as a masseur, claiming to treat diseases without pay, and as a matter of fact treat human beings for disease and disorder as a doctor and indirectly charge them therefor, without a registered certificate.—Milling v. State, Texas Civil Appeals, 150 S. W. 434.

CRIME AND ITS SOCIAL BASIS.

NEARLY ten years ago there died at Paris the eminent French jurist and sociologist, Gabriel Tarde. "To be recognized as an original thinker in three separate fields of knowledge—psychology, sociology, and criminology; to pursue successfully the careers of magistrate, statistician, and professor of political science—such an achievement is rarely to be recorded. It is a brief summary of the life work of Gabriel Tarde." With this lucid characterization is introduced the editorial preface to the English edition of Tarde's "Penal Philosophy,"* a work teeming with interest to all thoughtful students of social questions, particularly at the present time, when the reciprocal relationship of the individual and society challenges the attention of all.

One of the distinctive features of Tarde's philosophy was his protest against Lombroso's anthropological and physical theories of crime. He became the modern exponent of the Aristotelian doctrine that man is by nature a political animal. The mainspring of human action is imitation rather than the exercise of free will. According to Tarde, man living as a dependent unit of society is an automaton, but instead of being acted upon only by geographical, climatic, and other physical factors, he is the resultant of social forces. Imitation is the supreme factor in human life, and is all the more operative the greater the density of population. The inferior imitate the superior in dress, in language, in opinions, and in vices. Tarde points out how in former times the vice of drunkenness and the crimes of poisoning and murder which were the peculiar prerogative of the nobility became the inheritance of the common people. At the present day in a similar manner rural districts take their cue from the cities in fashions, in slang, and in viciousness.

One of the striking illustrations of the power of imitation or of suggestion in the production of crime is the occurrence of so-called "crime waves" following the publicity given by the newspapers to sensational crimes. The recent epidemic of attempted suicide by means of corrosive sublimate is another instance of the same law of imitation. Great is the responsibility of the public press and of the stage, which may exert a powerful educational influence, but which may become, as is so frequently the case, the means of disseminating among the young and impressionable the blight of immorality, and which may even become the direct incentive to wrongdoing. "Crime," says Tarde, "is a social phenomenon like any other, but a phenomenon which is at the same time anti-social, just as a cancer participates in the life of an organism, but working to bring about its death."

In these days when in spite of "peace" congresses war is waged as frequently and with as much ferocity as at any time in the world's history, it is interesting to note Tarde's definition of war as "the highest and most absolute possible expression of crime which has become a mutual affair." According to this view the soldier has evolved from the brigand just as the workman has evolved from the slave. Militarism is the collective substitute for the individual passions of hatred, envy, cruelty, and greed, which although separately condemned are in the larger aggregate justified and glorified as the means of national expansion or defense. Recent events in the Balkans apparently illustrate at least in part the truth of this statement. When engaged in a common cause against Turkey, the Balkan states and Greece fought with uncommon unity of purpose and mutual respect. Now with their hated foe subdued, the Allies are arrayed against one another, their native jealousies and hatred unleashed by the cessation of their common cause.

Of special interest to physicians is the doctrine of responsibility which Tarde erected as the keystone of his penal philosophy. He conceived of criminal responsibility as dependent upon two factors, personal identity and social similarity. The former represents the maintenance of the psychological unity or self with its multitude of elements—comprising obligations to one's self and fellows, a recognition of the heritage of the past and the duties of the present—all of which go to make up the identity of the normal individual. When this identity is impaired, when the consciousness of the individual is dissociated into its various parts, so that they no longer blend to form the harmoniously acting being, one is justified in saying that criminal responsibility is lacking. Social similarity is that factor in the maintenance of responsibility by virtue of which the individual does not act counter to the settled customs and conventions of the society in which he lives. A Fiji Island savage transplanted to our shores cannot be expected to at once act in accordance with the laws of his new neighbors. This lack of social similarity will absolve him from responsibility for any crimes that he may commit.

With this brief exposition of Tarde's conception of crime and of criminal responsibility one cannot adequately present even in outline the vast scope of the book which deserves careful reading by everyone who is interested in the delinquent, unfortunately an appreciable part of the social edifice.

*"Penal Philosophy," by Gabriel Tarde, late magistrate, and professor in the College of France. Translated by Rapelje Howell, of the New York Bar. With an editorial preface by Edward Lindsey, of the Warren, Pa., Bar, and an introduction by Robert H. Gault, assistant professor of Psychology in Northwestern University and managing editor of the *Journal of Criminal Law and Criminology*. Price $5.00 net. Boston: Little, Brown & Company, 1912.

THE MEDICAL COUNCIL OF CANADA.

Canada is to be congratulated on not being hampered by legal barriers in effecting a national registration law to regulate the practice of medicine, or rather on having in its medical profession the unity of spirit which has enabled it to bring about such a desirable law. Henceforth any one desiring to obtain a medical license which will grant him the right to practise medicine in any or all of the provinces of Canada without further examination may obtain the same from the Medical Council of Canada. This council is composed of members representing each provincial medical council and each university medical school. The qualification granted by the Medical Council of Canada will be known as the "License of the Medical Council of Canada" (L. M. C. C.), according to the first Announcement of the Council just issued. The council appoints examiners who submit the candidates to written, clinical, and oral examinations. One of the main objections to the introduction of thorough practical examinations in this country is the great expense. This will be met by the Medical Council in Canada by charging a fee of $100 for the examination. Whether or not it will ever be possible here in the United States to establish a like examining body whose license will be recognized and give the privilege of registration in each State is difficult to predict.

At present there is organized the Federation of State Medical Boards of the United States which is working to this end. We cannot have a national registration law without amending our federal constitution because Congress has no power to regulate the practice of medicine within any given State. All that Congress could possibly do now would be to pass a law that would be applicable to a doctor taking an examination in more than one State. Under our present constitution, reform on a national scale must come by all the States enacting uniform laws.

Many practitioners have suffered the annoyance of having to take examinations that are far from practical when they have moved to another State. By these physicians, if not by the rank and file of the profession, a national licensing body would be most welcome. It would seem that such a body could be established more quickly than to bring about a uniform standard for medical education and uniform laws in all the States. Many of the State boards might have moved rightly in the direction of recognizing high standard examinations conducted by colleges or other States if it had not been for the unfortunate introduction of the so-called reciprocity clause in many of the State laws. This reciprocity clause might better be termed the retaliation clause. A State which has an obviously lower standard then another State that refuses to indorse its license retaliates by refusing in turn to indorse the license of the higher standard State. This wrongful retaliation is deplorable. It is to be hoped that we may before many years be able to have a national licensing board similar to the Medical Council of Canada.

THE MEDICAL EXAMINATION OF ALL WORKERS.

This age is certainly the age of the cult of health. In every civilized country the attention that is being paid to the prevention of disease, to the preservation of health, and to the measures that are being taken to treat disease, increases day by day. Governments and municipalities are more than ever convinced that if the population is not healthy, decay from every point of view is sure to progress.

"Ill fares the land to hastening ills a prey,
Where wealth accumulates and men decay."

A convincing proof of this universal feeling was afforded recently, by the meeting of the British Royal Institute of Public Health. A paper read at this meeting by Dr. I. C. McWalter was especially deserving of notice. It dealt with the necessity for the medical examination of all workers and pointed out that the enactment of the Employers' Liability Act in Great Britain had altogether changed the views of the employer as to the health of his employees. Formerly the employer was callously indifferent to the health of the workman. Now, if the workman be stricken down at his work it will be presumed that the accident arises from his employment and it will go hard with the employer to prove otherwise; and if he die the employer will have considerable difficulty to disprove that death did not arise from the effects of his work. Further, the workman is insured and therefore has much to gain by keeping at work for a few months, because thereby he becomes entitled to sickness and disablement benefit after a certain interval. Thus the mere fact of a man being at work now endows him with certain privileges. He must be insured, and he must, in certain circumstances, get even a lifetime's disablement benefit, and consequently it appears fairly obvious that it is only a question of time when the workman in Great Britain will be compelled to undergo a medical examination before he is allowed to work.

Of course, ill health is a tax on the community, and it is to the ultimate benefit of all concerned that no person should be permitted to engage in any employment until he or she has been tested and found physically fit for work. It is argued that such regulations would press heavily on the poor, but it cannot be urged that it is to the real benefit of anyone that a sick person should be allowed to work. The examinations, it is to be presumed, would not be equally strict for all trades, and it is also well understood that the individual should not be permitted to suffer unduly for his condition of health, except possibly in the case of certain diseases. As McWalter shows, the advantage to the employer of such a system is obvious, while the advantage to the employed is yet greater. He omits, however, to draw attention to the fact that the advantage to the race should be the greatest argument in its favor. The days of natural selection, the survival of the fittest, have passed and now steps must be taken to conserve the population by the best means available, and it would seem that

medical examination of workers is logically one of the most important of such means.

It may be pointed out that this country, Great Britain and her self-governing dominions are the only civilized countries of the world which do not possess the advantages given by conscription. Whatever may be the drawbacks of conscription, the system at least has this in its favor, that when a man has to serve in the army he is medically inspected and tested.

Perhaps, on the whole, the laws of this country with regard to the health of working people are more lax than in any country, and although it is always being refreshed and replenished by new blood, by immigration, this mode of revitalizing is becoming of doubtful value. The type of immigration has changed completely of recent years, the new blood does not revitalize as formerly—to some extent it poisons, and, moreover, the conditions of life in the big cities are approximating those of Europe.

Present Status of Organ Transplantation.

At a recent session of the Berlin Surgical Society (*Berliner klinische Wochenschrift,* June 16) Stich gave a much needed sketch of this subject. Seven years ago Carrel began his autoplastic work, and it was thought highly probable that animal organs could be successfully implanted from an animal to another of the same species and from man to man. This held quite good for segments of blood vessels and in invertebrate animals the heads even could be exchanged. Carrel's experiments showed that neither homoplastic nor heteroplastic transplantation could be successfully made between vertebrates. The transplantates grow in, but degenerate within a short time. The only exception is tumor transplantation. In regard to homoplastic transplantation, this is said to be possible at times in animals which are consanguine. Many remarkable cases of homoplastic transplantation seemed for a while to have been successful. Carrel, Unger, Sajou, Ullman, and others have reported cases of kidney transplantation of all three types, some on human beings. Carrel and Unger have shown the practicability of homoplastic transplantation in animals, while quite a few cases of the heteroplastic type have succeeded. In human beings, he said, failure awaits either form of transplantation. It is claimed by Unger, however, that remarkable instances of prolongation of life as a result of transplantation justify occasional resort to the latter, when all other measures fail and the patient is still responsive to treatment. He implanted both kidneys of a large ape in a girl with uremia. The kidneys were permeable in thirty-two hours and showed no sign of degeneration.

A Depreciation of Psychoanalysis.

The healthy opposition to Freudian analysis—healthy because it only pursues constructive ends—is not only to be expected but invited. The doctrine is, however, like religious creeds and dogmas, temptingly easy to attack. At the recent annual meeting of the Deutscher Verein für Psychiatrie (*Deutsche medizinische Wochenschrift,* June 19) both Bleuler and Hoche so riddled Freud's theories that they and their kind tend to be under the suspicion of proving or disproving too much. Yet there seems to be no desire to be destructive. The burden of this and of all similar criticism is to drive the Freudians to abolish doctrines founded on minute, prolonged studies of the individual and to build up a general propaganda, applicable alike to all. Because prolonged study of one patient brings out a homosexual primary factor, we should not understand that this element is universally in evidence in psychoneuroses. Hoche sums up his critique in a series of propositions: thus the advocates of psychoanalysis are not able to furnish proofs of their doctrines; they confound analogy with identity; their course of procedure is arbitrary, and depends on chance; they do not care to argue with their opponents; while the faculties of the psychologists are sharpened by psychoanalysis, there is no corresponding increase in our knowledge of psychiatry; the method is very tedious, and wastes the time of physician and patient.

News of the Week.

City Death Rate.—For the week ending July 5, the death rate in New York City was 12.54 per thousand of population, representing a total of 1,291 deaths. This rate was 0.3 of a point lower than that for the corresponding week of last year, although the total number of deaths was increased by 18. Nineteen deaths were reported during the week as due directly to heat stroke, as against one in the same week of 1912 when weather conditions were more favorable. Whooping-cough and chronic heart and kidney diseases also gave an increased mortality. The infant mortality, however, was considerably decreased, the death rate for the entire city during the week being 89 per 1,000 births, as compared with 104 per 1,000 during the corresponding week of 1912. This represented a decrease of 35 deaths of infants under one year of age, and there was also a decrease of 45 deaths under five years of age. The death rate for the first twenty-seven weeks of 1913 was 14.94 per 1,000 as compared with 14.98 during the same period of 1912.

Health of the Canal Zone.—The report of the Department of Sanitation of the Isthmian Canal Commission for the month of May, 1912, gives the total number of deaths from all causes among employees as 38, of which 27 were due to disease and 11 to violence, equivalent to an annual average death rate per thousand of 7.63. For the entire population of the cities of Panama and Colon and the Canal Zone, including both employees and civilians the death rate for the month equalled an annual average death rate per thousand of 19.66, which is 0.65 of a point higher than for the same month of last year. Deaths from the principal diseases were as follows: dysentery, 1; hemoglobinuric fever, 1; lobar pneumonia, 5; organic heart disease, 3; tuberculosis of lungs, 1; typhoid fever, 2. During the month of April the Culebra Hospital and sick camp were discontinued, the dispensary alone being kept open. No cases of yellow fever, smallpox, or plague originated on or were brought to the Isthmus during the month.

Dr. Friedmann of Berlin, who, it may be remembered, was in this country last spring trying to effect the sale of an alleged cure for tuberculosis, has not received an over-warm welcome from the medical profession of his native town. Indeed, most of them repudiate him, quoting Dr. Mannheimer's report in the Medical Record in disproof of his claims. On his return to Berlin he had

recourse to the newspapers there, as he did here, in the endeavor to convince the laity that he had a sure cure for tuberculosis, but is apparently succeeding no better there than here. In New York he had to contend with the therapeutists, who found no signs of improvement following the administration of his remedy to the tuberculous. In Berlin it is the bacteriologists who are disproving his claims, asserting that his bacillus is not acid-fast and therefore fails to prove itself a member of the tubercle bacillus family.

International Opium Conference.—Secretary of State Bryan has requested from Congress an appropriation of $20,000 toward defraying the expenses of the International Opium Conference at the Hague, on the ground that the United States would be derelict in its fight against the opium evil if it did not participate in the meetings.

X-Ray Victim.—Mr. Burton E. Baker of Hartford, Conn., died at his home in that city on July 10 from injuries due to exposure to the *x*-rays in the course of his experimental work.

Bronx Hospital.—The trustees of the Bronx Hospital, New York, have recently purchased a site for the proposed building, consisting of five lots at the southeast corner of Crotona Park East and Charlotte Street, the plot measuring 125 x 105 feet. On this it is planned to erect, as soon as sufficient funds are collected, an eight-story building costing about $300,000. The Bronx Hospital corporation was organized about two years ago and has maintained a dispensary in which 30,000 patients were treated last year.

New Convalescent Home.—It is reported that Mr. Vincent Astor has purchased a site of ten acres at Rhinebeck, N. Y., on which he will erect, in memeory of his father, a home to be known as the John Jacob Astor Home for Convalescent Children. Plans for the buildings have not yet been completed, but it is probable that accommodations will be provided for one hundred children.

Hospital Fund Incorporated.—With the object of raising a fund to be used solely to acquire real property, erect buildings thereon, and endow them for the Washington Heights Hospital of New York, the Building and Endowment Fund Association of Washington Heights Hospital was incorporated in Albany on July 7.

Dr. William G. LeBoutillier of New York has resigned the office of chief surgeon on the staff of Major-General O'Ryan, because of the pressure of private business.

American Physicians in Paris.—The party of medical men who sailed from New York two weeks ago arrived in Paris on July 13. They were received by Ambassador Herrick on Monday and visited the Pasteur Institute and a number of hospitals. Their itinerary includes a visit to the principal clinics and spas of Germany and closes with attendance at the International Medical Congress in London, August 6 to 12.

Prize for Ophthalmology.—An anonymous donor has given 500 francs for a prize for researches on iritis and cyclitis. The papers (which may be in English) are to be sent to the editor of the *Annales d'Oculistique,* 26, Boulevard Raspail, Paris, before August 15, 1914.—*The Lancet.*

Atlanta Medical College.—By the consolidation of two of the larger medical schools of Atlanta, Ga., the Atlanta College of Physicians and Surgeons and the Atlanta School of Medicine, a new school has been formed to be known as the Atlanta College of Medicine. This was the title of the first medical school established in Atlanta, in 1854, which later merged with the Southern College to form the College of Physicians and Surgeons, in 1898. The Atlanta College of Medicine will have Dr. Willis F. Westmoreland, at present professor of the principles and practice of surgery in the Atlanta College of Physicians and Surgeons, as its president, and Dr. W. S. Elkin, now Dean and professor of gynecology in the same institution, as its Dean. Two other officials will be nominated by the Atlanta College of Medicine, and the faculty of the college will be selected from the members of the two institutions.

Obituary Notes.—Dr. Edward Everett Hyde, Assistant Editor of the *Journal of the American Medical Association,* died on July 4, after a brief illness, from myelogenous leukemia. He was born in Galesburg, Ills., Jan. 19, 1875, and was graduated from the College of Physicians and Surgeons, Chicago, in 1900. The same year he was ordained a minister in the Congregational Church and went as missionary to the Caroline Islands. Returning in 1902, on account of the ill health of his wife, he was appointed on the staff of the *Journal,* where he remained to the time of his death.

Dr. George Joseph Gorman of New York, a graduate of the New York University Medical College in 1891, and a member of the Department of Health of New York City, died suddenly at his home on June 28.

Obituary.

BENJAMIN LEE, M.D.

PHILADELPHIA, PA.

Dr. Benjamin Lee of Philadelphia, assistant commissioner of health of the State of Pennsylvania, died at his home in Point Pleasant, N. J., after a brief illness, on July 11, aged 79 years. Dr. Lee was born in Norwich, Conn., Sept. 26, 1833, and was graduated from the University of Pennsylvania with the degree of A.B. in 1852, receiving his master's degree in 1855 and his Ph.D. degree in 1878 after attending courses of the auxiliary faculty of medicine. He attended lectures at Jefferson Medical College in the session of 1853-54 and at the New York Medical College in 1854-56, being graduated from this institution in the latter year. From 1855 to 1856 Dr. Lee was resident physician to the Colored Home of New York City. In the following year he served as interne in Bellevue Hospital and in the winter of 1857-58 he pursued studies in the hospitals of Paris. In 1858 he made a study of obstetrics in Vienna under the direction of the late Karl Braun. Subsequently he returned to New York City, but after a professional residence of seven years he took up medical work in Philadelphia. Dr. Lee was a member of the 22d Regiment New York National Guard; assistant surgeon in the United States Army in 1861, surgeon in 1862. In 1885 he became a member and secretary of the newly created Pennsylvania State Board of Health and he continued in that relation until the Board was superseded in 1905 by the State Department of Health in 1906, when he became assistant to the Health Commissioner. He was secretary of the Pennsylvania State Quarantine Board from 1893 to 1905. He was for a time professor of Orthopedic Surgery in the Philadelphia Polyclinic and College for Graduates in Medicine. He supervised the sanitary medical service in and about Johnstown following the great flood of 1889. In the same year he was appointed United States Commissioner for the

Condemnation of Land for Quarantine Purposes at the Mouth of the Delaware River, and in 1891 he was appointed a member of the Quarantine Commission to select a site for a new station on the Delaware River or Bay. He was Health Officer of the Port of Philadelphia from 1898 to 1899. He was a member of the American Academy of Medicine, the National Conference of State Boards of Health, the American Public Health Association, the American Orthopedic Association, the Philadelphia County Medical Society, the Medical Society of the State of Pennsylvania, the American Medical Association, and the Mutual Aid Association of the Philadelphia County Medical Society.

HORACE JAYNE, M.D., PH.D.

PHILADELPHIA, PA.

DR. HORACE JAYNE of Philadelphia, formerly director of the Wistar Institute of Anatomy and Biology of the University of Pennsylvania, died suddenly at his home in Wallingford, Penn., on July 8, aged 54 years. The last years of his life were devoted to the preparation of a work on biology which is left uncompleted by his death. Dr. Jayne was graduated from the University of Pennsylvania, receiving the degree of A.B. in 1879 and of M.D. in 1882. After studying for a time in Leipzig and Jena, he was appointed assistant instructor in biology in the University of Pennsylvania, and in 1884 was made professor of vertebrate morphology, holding this chair until 1894, when he became director of the Wistar Institute. This office he resigned in 1905. From 1884 to 1889 Dr. Jayne was also secretary of the Faculty of Biology of the University, and from 1889 to 1894 Dean of the College Faculty. He was co-editor of the *Journal of Morphology*, the *Anatomical Record*, and the *Journal of Experimental Zoology*, and had written largely on anatomical and biological subjects. He was a member of the American Academy of Natural Sciences, the Society of American Naturalists, the American Philosophical Society, and a fellow of the American Association for the Advancement of Science and the Philadelphia College of Physicians.

HENRY JACQUES GARRIGUES, M.D.

TRYON, N. C.

ON July 7, 1913, at his home in Tryon, N. C., Dr. Henry Jacques Garrigues, formerly of New York, died after a short illness, aged 82 years. Dr. Garrigues was born in Denmark, and received his medical degree from the University of Copenhagen in 1869, coming to this country shortly afterward. He was for some years professor of obstetrics in the Post-Graduate Medical School, and professor of gynecology and obstetrics in the New York School of Clinical Medicine, and was foremost in the adoption of asepsis in maternity work. He was a member of the American Gynecological Society, an honorary fellow of the Obstetrical Society of Edinburgh, and a former president of the German Medical Society. During his active lifetime he was associated with many hospitals, and at the time of his death was consulting surgeon to the New York Maternity Hospital, consulting gynecologist to St. Mark's Hospital, and consulting physician to the Mother's Home. Dr. Garrigues had recently taken up the study of Esperanto, and had been elected president of the Esperanto Society of South Carolina.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

OFFICIAL RESEARCH COMMITTEE—HOSPITALS ASSOCIATION, SIR W. OSLER ON VOLUNTARY SYSTEM—AMENDING INSURANCE ACT—RESEARCH DEFENSE SOCIETY—A SURGICAL TRIP—HISTORICAL MUSEUM—DEATH OF JONATHAN HUTCHINSON.

LONDON, June 27, 1913.

THIS week it is officially announced that the Chancellor of the Exchequer has appointed a committee with executive functions to be known as the Medical Research Committee, for the purpose of dealing with the money available for research under the Insurance Act. The total of such money amounts to about £57,000 per annum. It seems that the recommendations of the Treasury Committee on Tuberculosis are accepted by the Chancellor. The chairman is to be Lord Moulton, F.R.S., who has extensive knowledge of science and a judicial mind, so that it is possibly better for the committee to be presided over by a non-medical person. The other members are Sir T. Clifford Allbutt, K.C.B.; Dr. Addison, M.P.; Mr. Astor, M.P.; Mr. C. J. Bond, F.R.C.S.; Dr. Wm. Bulloch, F.R.S.; Dr. Matthew Hay, LL.D.; Dr. F. Gowland Hopkins, F.R.S.; Col. Sir W. B. Leishman, F.R.S. These first appointments are for three years; in and after 1916 three members are to retire at intervals of two years, their places being filled (whether by reappointment or otherwise) by the minister responsible for national health insurance. The duties of the committee are to formulate the general plans of research for each year at its outset and make arrangements for carrying them out, to supervise them so far as necessary, and in particular to secure adequate co-ordination of the various parts of the scheme. The Chancellor has also appointed another body, an "Advisory Council," consisting of forty members, for which no one seems to see the necessity. It cannot be for the sake of finding posts for his friends, for he says he obtained suggestions for the names from all the universities, Royal College of Physicians and Surgeons, and other public bodies. Perhaps he was thinking of political bodies, but hardly so, for he is not obsessed with the notion that two chambers are needful for the constitution of such—indeed, he belongs to a cabinet which desires to restrict the power of the second chamber. Howbeit, he has set up this council with the duty of considering the committee's scheme year by year, submitting such criticisms and suggestions to the minister about it as they think advisable with a view of securing adequate consideration for the problems of research at home and abroad. You will observe that every proposal of the committee will have to be passed on to the Council, who forward it for final approval to the minister responsible for National Health Assurance. It is clear that this democratic politician means to retain complete control for himself and successors over the two bodies he is establishing. Lord Moulton is to preside over the council as well as the committee.

Yesterday Sir Wm. Osler presided at the annual meeting of the British Hospitals Association. In the course of his address he contrasted your methods with ours, extolling yours as much superior. He admitted, indeed, that our county hospitals were admirable. But he startled some hearers with an attack on the voluntary system. As you know this

has long been a feature on which most English people pride themselves, but his counsel was to "give it up, it is antiquated, and not likely to continue." We must, he said, make up our minds to take pay in the general hospitals and by way of encouraging us assured us there is not a general hospital in the United States or in Canada which does not take all the money it can get out of all classes of patients. In England, he said, everything is done for the poor who are rich in hospital care and comfort, but then the "poor rich" are the most neglected people in the country. He wanted every general hospital to have a private pavilion for these and was sure it would pay. This he followed with a severe criticism of our clinical and pathological arrangements which he would not say were out of date because they had never been in date. They must reform their ideas about many of them for they were pig-headed, obstinate, and hopelessly ignorant. Hospitals should be centers for the medical profession, and this could be promoted by linking up with the insurance scheme. If the hospitals were alienated from the panel doctors the only alternative would be a state service. Dr. Macintosh of Glasgow said before discarding the voluntary system they should show it had failed. Sir Hy Burdett said the unpopularity and perilous state of the insurance scheme was entirely due to the fact that such a revolution ought not to have been hurried through until the wisest and most experienced heads had been consulted. He suggested a plan for erecting pavilions on loan, but Mr. Alvey declared no sane hospital authority would borrow on such terms, adding that at his hospital (Charing Cross) the Act seemed to have decreased the outpatients and had no effect on the in. A majority of the societies would meet the hospitals fairly.

The bill for amending the Insurance Act has been brought in and read a first time. It deals with a number of small points and makes some concessions at a cost to the state of an additional £207,000 per annum, illustrating the evil of hasty legislation. Statutory authority is to be given for the additional grant made this year for medical benefit. Full medical benefit is to be continued to insured persons up to the end of life—not merely up to the age of 65. The 2s. 6d. per head given to insured persons is to be extended to uninsured members of all approved societies who were in receipt of medical benefit before the act. Medical and sanatorium benefit is to be provided out of the payments of employers for the 80,000 persons now exempted from insurance. These and other amendments were urged in the House, but Mr. Lloyd-George refused to consider them. He was so self-satisfied with his proposals that he thought it impossible to improve them. Now after two years he is compelled to ask the House to sanction amendments which he previously rejected with scorn. It is intended, after a second reading, to send the bill to a standing committee—a plan strongly objected to by the approved societies. These have previously made various requests which the government refused to listen to, and many are convinced that the administration of the act is likely to break down. They have asked for control of the medical benefits in order to cooperate with the practitioners and check sickness claims, but nothing has been done. They have urged the abolition of the costly division of the insured population into four national groups with four separate commissions and officers, rivaling each other in issuing circulars, forms, and various instructions. But again nothing results and the Friendly societies still have to carry on separate accounts. Some supporters of the government condemn this expensive system and admit that if no by-elections were pending the bill would not have been proposed.

The annual meeting of the Research Defense Society was held at the Royal College of Physicians on Tuesday, Sir David Gill (president) in the chair. In his presidential address he said that if people before joining antivivisection societies would but read the report of the Royal Commission on the subject they would learn the real truth about it. The proposal in one of the bills before Parliament that an inspector should be present throughout the whole course of an experiment was an insult to a class of honorable and humane men. Bishop Frodsham (a V.P.) said th society had done much to form a healthier public opinion on a work which had suffered much from misstatements. He held that from a Christian standpoint research was not only justifiable but an act of service to God. The Earl of Cromer entered a protest against the Society for Prevention of Cruelty to Animals for not re-electing Lord Cheylesmore on its council. He thought it was a "snap vote," due to Mr. Stephen Coleridge, and did not represent the mature views of the members generally. If he were mistaken as to that he should withdraw from the Prevention Society and hoped others would do the same.

The surgical section of the Royal Society of Medicine has followed the example of some other sections and held a meeting in the provinces. This was at Birmingham, to which about a score of London surgeons went and had a successful day at the General and the Queen's Hospitals, where both operations were witnessed and cases exhibited. Among these was a patient on whom Mr. J. T. J. Morrison had done an Estlander for empyema, several cases shown by Mr. G. Barling of tumors of the brain which he had removed, some of them years previously. Other interesting cases were by Messrs. Haslam, Heaton, Lucas, Billington, Nuthall, and Woodman. A paper or two completed the day's work and the staffs of the hospitals entertained their visitors at dinner, which important function was concluded in time for the last train to London.

We are talking of the approaching International Congress of Medicine which is to be held this year in London and we hope to make it as successful as any of its sixteen predecessors. There is to be a section for the History of Medicine, over which Dr. Norman Moore is to preside, and on Tuesday he opened a museum, which is to be a kind of side show of this section. It has been collected and arranged by Mr. H. S. Welcome and is intended to illustrate the development and progress of the healing art in all countries and in all ages. The wide range of the exhibits from prehistoric specimens down through the centuries to modern times affords an opportunity of study and amusement which many will doubtless enjoy. The great variety, too, will excite surprise and gratify curiosity. Think of a trifle like the first tooth brush, of relics like Livingstone's pocket case and his Bible, of Mungo Park's pocket case, and so on. Art, too, has many products illustrating the subject—models, statues, paintings, colored drawings, diagrams, books, instruments, and appliances of all kinds. Objects have been lent by the British and other museums, by the colleges and other institutions at home and abroad. This interesting collection will remain

open until September, but already there are ideas afloat that it might become, after the loans are returned, the nucleus of a permanent museum.

Jonathan Hutchinson died on Monday, June 23, in his eighty-fifth year, at his country house at Haslemere. It is needless to tell you the story of his great work—known to you and wherever surgery is cultivated. He took the double qualification in 1850, the F.R.C.S. in 1862, and the Astley Cooper prize in 1865. He was very early elected to a vacancy at the London Hospital, with which he continued his connection throughout his life, passing from the assistancy to the full surgeoncy and retiring as consulting surgeon and as Emeritus Professor of the college of that great hospital where his clinical work was carried on. He was president of the Royal College of Surgeons in 1889, and on his eightieth birthday the president and vice-presidents sent him a letter of congratulation in which they expressed their sense of the value of his varied contributions to surgical science and his devotion to the profession. Probably this indication of the regard in which he was held, not only by the fellows and members of the college, but by the profession throughout the civilized world, was more appreciated by him than the many honors which universities and societies conferred upon him as degrees, fellowships, and presidencies. In his early days his doorplate in Finsbury contained only the words Jonathan Hutchinson, in large letters reading across the door. When he removed westward he took the prefix Mr. on a smaller plate, but when, at eighty years of age or thereabouts, he received a knighthood he did not change the prefix to Sir. It seemed rather curious at times to hear him spoken of by non-medical persons as a specialist, one would say for this, another for that, and a third for something else. This, however, shows the wide reputation he had acquired and the variety of subjects to which he devoted his researches. He enjoyed for half a century an enormous field for clinical observation, and I think it was the patient cultivation of that which gave him so much fruit. He was further a diligent collector of whatever discovery or information would throw light on clinical problems. Museums attracted him. He founded one at Haslemere and another at Selby. They were mostly devoted to natural history and largely stocked and kept up at his expense. He used to say he would like to see one in every county. He also founded the Polyclinic—a post-graduate college which was deeply indebted to him not only for money but for help in the teaching and for its great collection of pathological drawings. Yesterday the funeral took place at Haslemere. The presidents of the two Royal Colleges and numerous representatives of the hospitals and other institutions with which he was connected attended the ceremony.

OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

INCREASE IN PLAGUE—MALARIA—TYPHOID INOCULATION—PERSONAL.

MANILA, May 10, 1913.

DURING the week ended April 26 there was a sharp increase in the number of plague cases reported in the city of Manila. Four deaths occurred within a period of 72 hours. One case was at No. 334 Calle Padre Rada, one at 1419 interior Calle Dagupan, one at 1364 Calle Sande, and one at 642 Calle Haya. On further investigation it was found that all of these persons worked in a silversmith's shop at No. 1364 Calle Sande. They were all employed on the first floor and this was found to be of cement. Ordinarily such construction would be regarded as rat-proof but owing to openings being found near the sides which resembled rat-holes, and cracks found here and there, it was deemed advisable to tear out the floor, which was done, and several mummified rats were found, whose death was probably due to plague, although this fact could not be definitely established. In addition to the four deceased persons, there was found another person at No. 1492 interior Calle Dagupan with malaise, headache and fever, who was regarded as a plague suspect and transferred to San Lazaro Hospital. Soon after admission to the hospital many of his glands became palpable and a few days later a definite diagnosis of plague was made, which was confirmed soon afterwards by autopsy. This individual also worked in the jewelry shop at No. 1364 Sande.

The foregoing experience illustrates in a striking manner the intimate relationship which exists between rat and human plague and that rat-proof construction must be kept in good repair. In this instance there is reasonable ground for believing that after the rat host of the fleas had died the fleas made their way through the cracks in the cement and attacked the workers in the shop. The premises were treated with petroleum on account of its insecticidal properties and then disinfected with a coal-tar emulsion. All the contacts were kept under observation for a period of ten days and no further cases have occurred.

It is also of interest to note that these human cases occurred in the district in which there was reported, over a month previously, a decided increase in the percentage of rat infection. Infected rats are still being found in the same section from which these human cases came, and the fact that there are not more human cases again illustrates the control which the modern sanitarian has over plague.

The regular monthly meeting of the Manila Medical Association took place in the amphitheater of the College of Medicine and Surgery, University of the Philippines, at 8:30 P. M., May 5.

The principal papers of the evening were read by Dr. T. W. Jackson and Dr. W. E. Musgrave, which formed a part of a symposium upon malaria at the San Jose sugar estate in Mindoro. This sugar plantation consists of many thousands of acres and is located in a section of Mindoro that since time immemorial has been known to be a hotbed of malarial fever. Several years ago when laborers were first introduced in large numbers malaria became so prevalent that for a while the prosecution of the work in connection with establishing the sugar mill and planting sugar cane was almost entirely frustrated, and even as late as last January it was reported that in spite of the sanitary efforts, the death rate still remained approximately 240 per thousand from all causes, the majority of the deaths, however, being due to malarial fever. It was stated that the habitations and the immediate area surrounding them have now been practically made free of mosquitoes, and that the next great step of the problem was to find the ways and means by which infected persons could be legally compelled to undergo treatment and the use of prophylactic doses of quinine enforced. The

authors of the papers were of the opinion that measures of this kind should be carried out. It seems, however, that there is no law at present in the Islands by which such a course could be enforced and that it would therefore be necessary to request the Legislature to pass the law to legalize the procedure.

Dr. Rembe of the Philippine General Hospital then exhibited two cases of meningocele which came through the ethmoidal sinuses and projected from the right side of the nose.

Dr. C. S. Butler of the U. S. Navy read a paper contrasting the sanitary conditions, especially with regard to typhoid fever, in the Florida army camp in 1898 and in the army camp in Texas in 1911. The author pointed out that he did not question the value of typhoid inoculation, but that he was of the opinion that the experience had in these two camps was not necessarily conclusive that the absence of typhoid fever in the Texas camp was due to the typhoid inoculation which had been practised. He laid special stress upon the fact that there were hundreds of cases of diarrhea in the camps of Florida while there were none in the Texas camp, and that this result could not have been brought about by typhoid inoculation. He also called attention to the small sick report and stated that the Florida camp consisted of volunteers, while the Texas camp consisted of regulars, who it was safe to assume were under better discipline. Investigation showed that there had been excellent camp sanitation in Texas, while the camp sanitation in Florida had been very poor. He also stated that the surrounding country of the Florida camp was heavily infected with typhoid fever, while in the vicinity of San Antonio typhoid was not very prevalent. In view of the foregoing, it would be impossible to state that the absence of typhoid fever was necessarily due to the typhoidinoculation which had been carried out.

Assistant Surgeon Julian Gillespie of the U. S. Public Health Service, who has been on duty as quarantine boarding officer in Manila, has been ordered to Hong Kong for duty in the American Consulate.

Dr. John E. Snodgrass of the Bureau of Health has returned from an extended leave of absence in Australia and the United States, and has been assigned as assistant to the Director of Health.

1. Some Abuses in Surgical Practice.—H. Gage notes that the glamour of surgery, its directness of attack, and its tangible results make it particularly attractive to all medical students, and inspire the majority of them with an ambition to practice it. Surgery, too, occupies by far the larger part of our hospital equipment, and has led to the establishment of numerous small community hospitals, which are chiefly surgical, one of the most obvious results of which has been that the local practitioner feels obliged to undertake surgery, just as he feels obliged to undertake obstetrics in order to protect and develop his general practice. Sir Patrick Cullen's observation, "that chloroform has done a lot of harm, it has enabled every fool to become a surgeon," has become still less an exaggeration of the truth since the discovery of asepsis. Active interference has been invoked for the relief of all sorts of disorders, both functional and organic, in many cases with but little justification, and major surgery has been freely practised by men whose training and opportunities for the observation and interpretation of living pathology have been far from adequate. Moore is quoted as stating that "some operations should be radical, but no surgeon should be so." Hasty snap-shot diagnoses have certainly led to much ill-advised and unnecessary opening. It seems that the purely mechanical side of surgery has been receiving far too large a share of attention. One must not forget that "any operation which does not better the condition of the patient must be regarded as a therapeutic error," and that to possess a sound judgment as to the indications and counter-indications for operations, based upon a careful and thorough knowledge of the natural history of disease and of surgical pathology, is far more important and valuable than the acquirement of mere mechanical skill.

3. Intestinal Stasis.—E. G. Schlesinger presents the views of Arbuthnot Lane and his school upon this subject. He states that clinically, cases of intestinal stasis fall more or less naturally into four groups, which one may term "the obstructive," the "toxic or suprarenal," the "mixed," and the "end-result" groups. The "obstructive" type is usually regarded as having a duodenal ulcer, a gastric growth, or what is known as "nervous dyspepsia." The patient, more usually a man, complains of pain after food, sometimes at once, sometimes after an interval, with vomiting, which usually relieves the pain. On examination the patient is very tender over the duodenum and points to this as the site of his pain. He may or may not complain of pain in the iliac fossa, but the patient is invariably extremely tender on pressure in this region, and the end of the ileum is readily palpated as a thick tender cord. A discriminating *x*-ray examination shows a firmly fixed point in the ileum, and a dilated and hypertrophied duodenum. The effects of ileocolostomy on this type of case are most striking. The second group of cases, the "toxic" or "suprarenal type," occurs more generally in women, and is the group most commonly recognized. In these people constipation is generally present, and, unless it has led to that condition of irritative diarrhea and paralytic secretion commonly called mucous colitis, is often extreme. The direct abdominal symptoms, apart from the constipation, are, however, overshadowed by the group of symptoms called toxic. Chief among these symptoms is a condition of mental depression and general misery, which is only increased as measure after measure that promises relief is tried, and the econdition grows steadily worse. This type of case shows as a rule marked pigmentation, a low blood-pressure, cold and clammy hands and feet, and marked general asthenia. Vomiting is practically constant, but differs from the obstructive type in not being related to food and in consisting usually of a watery fluid. The "mixed" group of cases includes these patients who present a mixture of the obstructive and the toxic symptoms. The group to which the term "end result" is applied is a large and varied one, consisting of cases in which the end result has reached such proportions as to overshadow the underlying cause. This group includes cases of such diverse nature as trigeminal neuralgia, many cases of dementia, of gallstones, and pancreatitis, and many cases of cancer of the breast, etc.

4. Blue Sclerotics and Osteoporosis.—F. A. Conlon asserts that hereditary blue sclerotics are always associated

with osteoporosis. In the author's cases these peculiarities were transmitted through five generations. From a study of his own and others' cases it is noted that the blue sclerotic is a result of direct transmission. What Bateson calls the "knight's move" in heredity, transmission to males through unaffected females never occurs. There is no skipping of generations. In other words, no member with a white sclera ever transmits the blue sclera to his offspring, but breed true. This is in accordance with the Mendelian laws of heredity. In the author's cases the blue sclera seems to be a dominant character.

7. **Separation of Metacarpal Epiphysis.**—W. P. Coues believes that increased care and thoroughness in the examination of the injuries about the carpus in children, with good *x*-ray pictures, will probably show an increasing number of separations of the epiphysis of the first metacarpal bone. This injury in children may take the place of the Bennett fracture in the adult. Union with some displacement of the epiphysis does not seem to affect the usefulness of the hand to any marked degree.

1. **Action of Testicular Extract.**—A. J. Smith and W. J. Crocker found that as the result of injecting a salt solution extract of cock's testis into the subcutaneous tissue of the hen the comb in most cases actually increases in size, both in the flat outline and in thickness. The combs brighten; the wattles in correspondence enlarge and brighten; in some of the hens the neck feathers become somewhat more brilliant; and slight growth and brilliancy of color appear in the small feathers at the base of the tail; in one a slight but distinct growth in spurs is recognized; the production of eggs diminishes; some of the hens become combative, and several times individuals are seen to attempt to cover the other hens after the manner of the cock. The observations are suggestive of the credibility of the idea that upon some internal secretion from the testis, a hormone, the prominent secondary sex characteristics of the male bird are dependent.

7. **Nontuberculous Apical Lesions.**—M. Fishberg believes that unilateral apical signs which simulate those characteristic of pulmonary tuberculosis are not as rare as is generally supposed. In mouth breathers one often finds retraction of the right apex, dullness, altered breath sounds, and even râles which are circumscribed and localized, giving a clinical picture of pulmonary tuberculosis; and the patient is often treated for a considerable time as being tuberculous. Many of the rapidly cured incipient cases are, in fact, instances of collapse atelectasis of the apical parenchyma due to interference with the entrance of air into the right apex in mouth breathers. Collapse atelectasis and induration are to be borne in mind in all right sided lesions of the lung apex occurring in mouth breathers, showing no tubercle bacilli in the sputum, and manifesting no tendency to follow the usual course of pulmonary tuberculosis, with fever, night sweats, tachycardia, malaise, languor, progressive loss of weight, etc. In such cases the fact that the patient has been working all along in spite of his cough, which may date back to childhood, and has developed physically at a normal rate, speaks very strongly against tuberculosis, and the apical signs are indicative of collapse induration. Physical signs of a lesion at one apex occurring after an attack of influenza, or met with in persons with pulmonary emphysema or defective muscular development, especially in young women, and among indoor workers generally, should not be hastily pronounced as indicative of tuberculosis. It must always be borne in mind that a person who never coughs and has suffered no progressive loss of weight, anorexia, malaise, etc., for months before the onset of an attack of grippe, may have a simple localized apical catarrh giving signs simulating those of incipient pulmonary tuberculosis, although it is not due to acid fast bacilli. On the other hand, the vast majority of cases of tuberculosis give a history of several attacks of "grippe," or "colds," extending over several months or years preceding the last "cold," which, in their opinion, was the beginning of their present illness. Clinical observation for a few weeks, with the judicious use of the thermometer and several examinations of the sputum, usually clears up the diagnosis even in cases in which the physical signs persist for months.

5. **Colloidal Gold Chloride Test in Congenital Syphilis.**—C. G. Grulee and A. M. Moody conclude that while from their small series of cases one cannot show that the gold chloride test gives specific reactions in cases of cogenital syphilis, one would seem justified in making the statement that the reaction is very suggestive and may prove to be of much more value in the diagnosis of congenital syphilis than any laboratory reactions previously projected. One must not lose sight of the fact, however, that laboratory tests of the nature of the gold chloride reaction must always be regarded only as an aid to clinical diagnosis. From the cases reported by the authors it would seem strongly suggestive that a case showing clinical signs of congenital syphilis could be confirmed by the reaction of the cerebrospinal fluid to the colloidal gold solution of Lange. It is possible that treatment will distinctly modify this reaction but to a much less degree than it would the Wassermann reaction.

7. **Suprarenal Extract in the Treatment of Renal Hemorrhage.**—H. L. Kretschmer enumerates the advantages of this method of treatment as follows: If by this simple procedure one is able to control the renal bleeding, the condition of the patient's urine may be studied at a time when it is free from large quantities of blood. In cases in which there is a severe degree of secondary anemia, due to the loss of large quantities of blood, the patient may be put on a general tonic treatment besides

the suprarenal extract treatment, until such improvement is reached as will render operation a safe procedure. This method of treatment may be the means of avoiding nephrectomy. It may be employed temporarily, at least until a positive diagnosis of the cause of the bleeding can be made.

10. Classification and Treatment of Nephritis According to Functional Tests.—M. Goldsmith describes Schlayer's recent experiments in testing the elimination of iodine, sodium chloride and milk sugar through the kidneys. Following a series of animal experiments it was ascertained that in persons with healthy kidneys the three substances were eliminated at a definite rate: 0.5 gram of sodium or potassium iodide in from forty to fifty hours, 10 grams of sodium chloride in thirty-six hours, and 2 grams of milk-sugar in four hours. In applying the tests to nephritics it was found possible to divide the cases into those with normal elimination of salt and iodine, but with delayed elimination of milk-sugar, and those with normal milk-sugar elimination but delay in the excretion of salt and iodine. Each group has associated with it certain clinical manifestations of nephritis which are not found in the other group, all indicating that the two types of nephritis occur distinctly in the human being, similar to the experimental forms produced in the lower animals. By means of these tests, in combination with the clinical features, all cases of nephritis may be classified as tubular, vascular, or azotemic. Such a classification is of value from the viewpoint of treatment. Many cases are found in which a combination of types exists, but one type always predominates and indicates the special line of treatment. Treatment, to be rational, should aim to spare that part or function which is especially incapacitated. This may be accomplished by excluding chlorides in tubular nephritis and nitrogenous food in the azotemic variety, and restricting, or excluding fluids in the vascular form.

6. A Practical Method of Growing the Acne Bacillus from the Comedo for the Preparation of Vaccines. T. H. C. Benians.
7. A Plea for the Appointment of a Royal Commission on Venereal Disease. Sir Malcolm Morris.

1. Relation of Influenza to Bronchitis and Tuberculosis.—A. J. Jex-Blake concludes that one should be slow to content oneself with diagnosing any acute febrile catarrh of the respiratory system as "influenza" unless the disease is about in epidemic form, or unless the patient's discharges show a pure culture of the *Bacillus influenzæ*. Unless these precautions are observed it is probable that the attack will in all probability be an acute infectious catarrh due to other microbes as the tubercle bacillus, the pneumococcus, *Micrococcus catarrhalis*, staphylococci, and streptococci. The second conclusion to be drawn is far more important than this form from the practical point of view. It is this: that to diagnose "influenza" rashly and readily entails a great risk of overlooking the early stages of pulmonary tuberculosis—a most serious matter for the health of the patient and for the credit of the medical practitioner. The outlook and prospects of recovery in tuberculosis of the lungs depend very largely on getting suitable treatment applied at the earliest possible moment, before the pulmonary lesions have advanced far. The author's figures show that in no less than 112 out 416 unselected cases of tuberculosis of the lungs the onset of the disease coincided with an attack of "influenza"; the frequency with which this occurs shows that it cannot be a mere coincidence. It is obvious that to make a diagnosis of "influenza" when the case may very well be one of pulmonary tuberculosis—as, indeed, it appears to have been in 264 out of my 1058 instances—must give a false sense of security to both patient and medical man, and must make the latter prone to overlook the more serious disease. Yet the two can be distinguished from one another with certainty, if not by the physical examination of the patient, at any rate by the examination (or by repeated examinations, if need be) of the sputum for tubercle bacilli. In other words, one ought to make sure that pulmonary tuberculosis has been excluded before resting satisfied with the diagnosis of "influenza" or "influenzal bronchitis."

2. Dietetic Treatment of Gout.—A. E. Garrod ventures to express a doubt whether by dieting gouty patients we achieve nearly as much as we think we do. It must be confessed that among hospital patients who could not, if they would, follow out any strict rules of dietary, who seldom pay heed to our advice that they should give up beer, and who, as soon as an acute attack is over, revert to their previous habits of life, the course of gout does not seem to differ materially as regards the character, frequency, and severity of attacks from that followed in people who are able to adjust their living according to the best advice to be obtained. Errors of diet are not the only factors at work in the causation of gout, and regulation of diet is only one of the means available for its control. Temperance in all things, and not in eating and drinking alone, is the golden rule for the avoidance of this disease and its manifestations. And even such temperance may not avail him who comes of thoroughly gouty stock.

5. Sensitized Vaccine in Bacterial Infection.—M. H. Gordon finds that the method of Besredka has the conspicuous merit of producing immunity in animals rapidly, without discomfort, and without producing any preliminary diminution of resistance. The experience of the author with cases suffering from bacterial infection goes to show that, where there is latent power available in the general resistance of the patient, the method has a similar effect on man under these circumstances. In some instances, moreover, this dormant power of the specific resistance may be awakened by sensitised vaccine even at a comparatively late stage in the attack. In cases in which the treatment did no good there was no evidence to show that it did the slightest harm. The method should have a great future prophylactically in the face of epidemics. It seems possible that sensitized vaccine may also be useful prophylactically in hospitals—e.g., by this means the resistance of the patient might be raised to *Bacillus coli*, *Streptococcus pyogenes*, or the pneumococcus before operations on the alimentary tract or other infected area. Similarly, the method is open to the physician for the purpose of preventing secondary infections. Further, a prophylactic dose of sensitised vaccine might be given to cases of difficult labor. Finally, in cases already infected the evidence brought forward shows that in a proportion of instances it is possible by this method to materially promote the patients' recovery. By administering a sensitised vaccine to these patients, one brings into action available reserves in that complex and still incompletely defined entity, the patient's specific resistance.

1. The Diagnosis and Treatment of Dysentery. Sir Charles Pardey Lukis.
2. Miners' Nystagmus. T. Lister Llewellyn.
3. Amino-acids and Sugars in Rectal Feeding. A. Rendle Short and H. W. Bywater.
4. The Experiences of a Medical Adviser under the Insurance Act. B. M. H. Rogers.
5. The "Controlled" Use of New Tuberculin in the Treatment of Pulmonary Tuberculosis. A. C. Watkin.

1. Diagnosis and Treatment of Dysentery.—Sir Charles Pardey Lukis differentiates as regards their symp-

tomatology bacillary from amebic dysentery as follows: (1) Bacillary dysentery is always acute in onset, and it runs a rapid course in nearly all cases. Amebic dysentery, on the other hand, even though it may begin with an acute attack, always runs a chronic course. It is therefore the form one is most likely to see in this country. (2) In bacillary dysentery pyrexia is common; in amebic dysentery it is rare. (3) In bacillary dysentery toxemia is a marked symptom; in amebic dysentery it is absent except when a liver abscess is forming. (4) In bacillary dysentery the stools are mucopurulent, with a large cellular exudate and small in bulk; in amebic dysentery they are grumous, like those of serous colitis, they are copious, and they contain little or no cellular exudate. (5) Liver abscess never occurs in bacillary dysentery; it is a common complication in amebic dysentery. In bacillary dysentery one may adopt either the saline or the bacteriological methods of treatment, but in the amebic form of the disease one must rely upon ipecacuanha or emetine. The bacteriological treatment consists of the use of a vaccine or of an antitoxic serum.

3. **Amino-Acids and Sugars in Rectal Feeding.**—A. Rendle Short and H. W. Bywater state that the older observations on the absorption of foodstuffs from rectal enemata, based on the analysis of rectal "washouts," are unreliable. The daily output of nitrogen in the urine of patients given nutrient enemata of milk or eggs peptonized for twenty or thirty minutes demonstrates that almost no nitrogenous matter is absorbed. Modern physiological opinion holds that proteins are absorbed principally as amino-acids. The failure of the rectum to absorb ordinary nutrient enemata is largely due to the fact that peptones are given instead of amino-acids. Chemically prepared amino-acids, or milk pancreatized for twenty-four hours so that amino-acids are separated, allows of a much better absorption of nitrogenous foodstuffs from the rectum, as demonstrated in five cases by the high nitrogen output in the urine. The low output of ammonia nitrogen shows that this high output was not due to the absorption of putrefactive bodies. The rectal washings were not offensive. Dextrose is much better absorbed than lactose, and relieves the acidosis due to starvation. Fat is not well absorbed. Scarcely any of the fat of ordinary milk enemata is retained. The best nutrient enema consists of milk pancreatized for twenty-four hours, with the addition of 5 per cent. pure dextrose.

Münchener medizinische Wochenschrift.

June 17 and 24, 1913.

Abbott's Treatment of Scoliosis.—Erlacher, an assistant of Spitzy's, sums up this subject briefly as follows: Abbott himself has shown by photographs and radiographs that he has completey cured very bad scleroses, some of which have remained healed and have gone without any sort of corrective apparatus for two and a half years. Naturally the duration of treatment of Spitzy's cases is too brief for comparison with those of Abbott. Nevertheless they have thus far filled the requirements expected of them and the results are superior to those of the older methods. There are certain types of curvature which it cannot hope to reach.

Puerperal Sepsis Cured by Operation.—Brix reports the following case: After evacuating the uterus for an abortion, the temperature rose. The patient continued to feel well for some days but was seen to be weakening. A radical course was then executed. Laparotomy was made on the very fleshy patient, who was then but in the Trendelburg position. After due preparation, the peritoneum was divided over the right hypogastric artery and vein. Both were simply ligated. The process was repeated on the other side. The entire uterus was now extirpated down to the vagina, and the end of the latter clamped. The peritoneal incisions were now nearly closed by continuous suture, so that a funnel was formed by traction on the sutures which were allowed to lie in the vagina, a device being used to prevent slipping upward. Convalescence was smooth. There is no mention of thrombophlebitis in connection with this case.

Sudden Death in Labor from Acute Pancreatic Necrosis.—Saenger writes at length on this subject. Many cases of sudden death during or just after labor are upon record; and when the subject of pregnancy toxemia was first discussed, it was surmised that some at least of these cases would be found due to this cause. Still later the use of drugs to produce the half sleep so-called—scopolamin and other narcotics as well as hypophysis substance as an oxytoeri were likewise held in suspicion. Mere coincidence seems responsible for what is known as false eclampsia, in which meningitis, pneumonia, etc., cause death at or soon after labor. A few cases are known to have been due to air embolism. The author now describes a case due to acute necrosis of the pancreas. We know little about the nature of this affection. The patient was corpulent and somewhat of an alcoholic. She ate very heartily just before labor began and the latter lasted but two and one-half hours. The introabdominal pressure must have been very high so that the pancreas was compressed. Soon after expulsion of the placenta she collapsed and vomited, death occurring so soon after that air embolus was suspected. Autopsy showed that the pancreas was the seat of an acute necrosis. There were fresh, toxic lesions in the liver, due apparently to the escaped pancreatic ferments; but there had been no pancreatic hemorrhage. The author finally asks whether this pancreatitis could have been due directly to the toxemia of pregnancy and is obliged to confess his inability to throw light on the subject.

Differential Diagnosis of the Poxes.—Bäumler writes of the differentiation of small pox, varioloid, varicella, and vaccinia, according to the most recent data. All depends on early recognition of small pox in one of the other forms. Wherever there is much exchange of travelers we have of course to look for small pox, along with typhus and cholera. Not much new matter is brought out. The existence of typical varicella in adults, apparently unheard of in some quarters, is not so rare in others. He refers the reader to Rickett's and Byle's atlas for a series of plates, which illustrate adult varicella and is about to have this work appear in a German edition. Occasionally epidemics of supposed measles have proved to be variola or varioloid. The distribution was not that of measles, for the efflorescences appeared on surfaces exposed to irritation and the effects of compression and gravity. We are taught about the forehead and cheeks as seats of predilection in variola; but authors do not often speak of a little isolated patch or row of vesicles where pressure or irritation has occurred. This phenomenon is of great value in differential diagnosis. The simultaneous outbreak in delayed vaccination of vaccinia and variola, together with the weakened "varioloid" which develops after vaccination with brief protective power, were known to Jenner as well as to any modern, and are still as difficult of differentiation.

New View of Sciatica.—Stoffel believes that in this affection certain paths in the sciatic nerve are at fault. If we can locate and isolate these nerve fibers we can cure the entire disease. If centripetal fibres are involved in the process a certain amount of scoliosis develops, and undergoes involution if the affected nerve tissue can be removed. He knows no such thing as a sciatic nerve, but instead a cable of individual nerve fibres, with motor and sensory, which have to do with the rear aspect of the lower extremity. So also he knows no disease sciatica

but only neuralgia as it affects one or more of the sensory paths. Before operation it is of course necessary to map out the location of the affected nerve paths. These are thereupon carefully mobilized, in order to avoid injury to motor tracts. The sensory path is first resected whereupon its ends are so treated that reunion cannot occur (this latter step may not be necessary). With this resource the author has succeeded in terminating the pains of sciatica, as well as all other symptoms of the latter. As in Foerster's operation the expected analgesia did not develop to any unpleasant degree nor have any trophic changes been noted. The sensory path left behind undergo degeneration, which prevents all possibility of rerudescence of symptoms.

June 23, 1913.

Serodiagnosis of Pregnancy.—Rosenthal of Budapest has for two years past made use of the antitrypsin reaction in the diagnosis of pregnancy. When the reaction is positive this indicates simply an increased metabolism of protein matter, and since this is known to occur in gestation we have the application of a general reaction to a particular case. The test is also negative when pregnancy is absent. After narrating documentary cases the author seeks to compare the antitryptin with the Abderhalden reaction. The latter, thought at first to be specific, has later been pronounced by Abderhalden himself as having diagnostic value in numerous other affections. As we continue to compare these tests it becomes apparent that the methods are sufficiently analogous in their nature to furnish the same type of results in the healthy subject. In diseased conditions departures are shown, but in the healthy gravida the two argue closely. The antitrypsin reaction gives a positive result in 30 minutes while both of Abderhalden's methods (optical and dialytic) require hours. In the case of conception in diseased women the two tests may be used to corroborate each other. Gottschalk, in an article on Abderhalden's dialysis method, states that he has employed the latter in 43 women, nine of which were not pregnant. Twenty-one women were gravid in the first two months. All of these gave a positive ninhydrin reaction. So far nothing more could be asked of a test. But it happened also that two nongravida gave a positive reaction. In both of these there was a history of abortion, the uterus was enlarged, etc. The positive test in such cases was a paradox, the author can only insist there the positive test could not have been due to errors of technique.

Functional Tests of the Liver.—Isaac reviews the recent literature of this subject. To test the work of the liver we are dependent on changes in the blood and urine. As the N of the nutriment passes through the liver we must study the mutual changes suffered by each, if the one be in great excess, and the other crippled. Under normal conditions, the urinary nitrogen should have the following partition: urea, 85-88 per cent.; ammonia, 3-5 per cent.; amino acids, 3 per cent., and the balance uric acid, kreatinin and similar bodies. Many attempts have been made to see to what extent extensive disease of the liver affects the nitrogen partition. The results are as good as negative—working beyond a doubtful fluctuation in the ammonia. Alkalies inwardly are said to cause all the ammonia to disappear from the urine. Others have recently asserted that in certain hepatic diseases there is increase in the urine of the nitrogenous acids. An artificial "acidaminuria" may be produced by feeding with these bodies, and this fact may prove useful in liver testing. It has been known for 70 years that in acute atrophy of the liver the urine contains large quantities of amino acids; so that in general disease of the liver an increase in the nitrogenous acid should be natural. Tests of hepatic activity with glucose, galactrose, etc., have been very extensively practiced. The production of an artificial glucose fever in disease of the liver and gall-bladder is sometimes noted. In general the finds with sugar testing are not at present reduced to harmony, and the subject is bound up with hyperglykemia. Urobilinaria, long known as evidence of hepatic insufficiency, is still the most familiar resource. However while it is never absent in hepatic disease, it may be present under other circumstances.

Nature and Treatment of Heat Stroke.—Hiller discusses this subject from the viewpoint of a German Army officer. Victims of heat stroke are most psychoneurotic. In addition to the duplex picture of relaxation and exhaustion, they present many hysterical and neurasthenic symptoms. The heat swoon is the simplest type of heat stroke, and in a sound subject the treatment—that for ordinary syncope—is quite sufficient. A psychopath on the other hand may suffer for several days with paresthesias, motor pareses or disturbances of special senses. These usually yield to a few doses of aspirin. Among soldiers, where many suffer from heat stroke while marching we find special types peculiar to the men concerned. The mildest type is one of relaxation, which is a preliminary to the severe forms, and hence serves as a warning. When these men are placed at rest the breathing and cardiac action becomes quiescent, and in from half an hour to an hour. There need be no treatment. With recovery there is profuse perspiration, which should be encouraged by freely drinking. Strong coffee is greedily drunk. The next degree or asphyctic form is that most commonly encountered. Since the soldier is making great exertions in a hot and humid atmosphere, and his respiration and circulation alike suffer, with resulting cyanosis. He falls and is found apparently lifeless and cyanosed. No time should be lost with other measures but one must proceed at once to artificial respiration, maintained if necessary for two hours. Under this management some of the most desperate cases have recovered. Cold affusions are mentioned but nothing of cooling the temperature with ice. The heart stimuli preferred are digitalis, strophanthus and caffein. A third form of heart stroke in troops is the socalled dysercrasic-paralytic. This occurs in those who have not been prostrated by the forms already mentioned. The most characteristic symptom is abolition of the perspiratory function. These are the cases of extreme temperatures (44° C). The term dyscrasic refers to the altered state of the blood. Aside from dry skin and fever, we note anuria, coma and convulsions (epileptiform), vomiting, motor pareses. While other measures are useful, a copious venesection is lifesaving. Next in order is saline infusion.

Injury of Bones from Steinmann's Nail-Extension.—According to Wagner this method of treatment has been almost faultless and when we consider its field of uselessness in ancient badly united fractures and other rebellious types it must be regarded as a decided advance in the treatment of these cases. However infection may result now and then as shown in the following case: A middle-aged man sustained a fracture in the middle of the right femur, with much displacement of broken ends. Bardenhener's extension method had to be given up on account of bedsores. Hirschberg's nails were then applied by Steinmann's technique, the nail penetrating the bones. But while firm union occurred, the points of exit and entry of the nail refused to heal, leaving fistulas. Three years later the fistulous tract was opened and found to communicate with a cavity in the centre of the femur. This was laid bare when the exposed surface filled with granulations and healed with a firm scar.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

Adapting the Policy: The policies issued in former years were full of exceptions which provided that under certain conditions the claims would not be paid. This custom has been supplanted by the removal of most of the restrictions and by the issuance of a variety of contracts in which there are about as many privileges as there were limitations in the old ones. The prospective applicant will seldom understand the nature of the conditions and privileges of the modern policies without assistance.

The intending insurer will usually choose the plan in accordance with the advice of the agent. It will be at once impolitic and injudicious for an examiner to intrude with advice of any sort whenever an agent has approached and solicited an individual, as the latter should be considered the more competent judge through his special knowledge of the subject and he will naturally resent interfernce.

Examiners are expected by their neighbors and constituents, especially in the smaller communities, to be more or less conversant with the methods and forms of insurance in vogue. Only a few examiners, however, have had an opportunity to inform themselves on this subject, but if they have studied the previous articles on the elementary principles of insurance they will have gained a sufficiently good understanding of the subject to enable them to impart some advice to those who are uncertain and who have not yet been interviewed by an agent.

An individual should not only be wise enough to insure his life, but he should also take the form of policy best adapted to his own circumstances. Even when the choice of policy has been made through the good offices of an agent, the applicant has not always succeeded in securing a policy fitted to his individual needs. The chief reason for this lies in the fact that some agentss are what are called "One policy men." They have studied a certain form of policy, sincerely believe in it, and are enthusiastic about it. They, therefore, have convinced themselves that everybody should believe in it. The companies have no preference as to what plan is chosen when good risks are offered.

Term Insurance: In this form the insurance is for a certain number of years and the premiums are based upon the mortality of these years only, not of the entire life. Like fire insurance, the contract expires at the end of the term unless the insured has died previously. This kind of insurance is adapted for those who must have protection at a low initial cost for a certain number of years.

After three or four years, however, this advantage of the term over more desirable forms of policies is practically lost, as the larger dividends of the latter may be devoted, then, to reducing the premium and thereby afford protection at about as low a net rate.

The companies will usually scrutinize the applications for term insurance very closely on account of the danger of adverse selection by those who have some reason to believe they will not live long and trust to the possibility of their physical weaknesses escaping detection by the examiner.

Those who can afford to pay more should select a form of policy in which some permanent benefit and ease of mind will accrue to themselves as well as to their dependents. Loans, as a rule, are not made on term policies and there is no surrender value in the way of continued insurance, paid-up insurance or cash in the case of default in payment of the premium. Another feature, often unsatisfactory in the ownership of a term policy, is the expiration of the contract at a set time. This is apt to leave the individual who has become an impaired risk in the meantime and to whom insurance is still a necessity in an unenviable plight. On the other hand, the policyholder usually has the privilege of changing to more desirable forms of policies without medical examination during the first few policy years. If this privilege of changing were permitted in the later years of a term policy, it would give too good an opportunity for adverse selection.

(The entire subject of Adapting the Policy requires more space than can be given in this number. The concluding remarks will be discussed in the next contribution.)

Death Rate of Middle Life.—One of the memories of the days of our childhood is the number of middle-aged and old people we were accustomed to see in the homes of our friends and on the streets of our towns and cities. When we make a mental note of this and compare it with the number seen to-day we realize the effective difference, since notwithstanding the difference in the modes of dress and customs tending to make youthful in this generation, there is a decided decrease in the middle-aged and old population. Dr. J. T. J. Battle (in a paper read before the Medical Section, American Life Convention, Hot Springs, February, 1913) ascribes this marked decrease to the difference in the manner of living and to the habits of excessive eating and drinking indulged in by the people of to-day. Statistics bear out his statements. During the past two or three decades, the increased mortality after 40 years of age is somewhat astounding. It is from 20 to 25 per cent. and is on the increase. This frightful death rate is principally caused by diseases of the kidney, liver, brain, and vascular system, practicaly all the organs susceptible to influences brought to bear through abuse of the digestive tract. Not these alone, but the high rate of tension at which we live, demanding more and more strain from our nervous systems, hence more restraint on our dispositions and a consequent decided laxity in our general ideas of life and its true values; all these are marked causes for shortened lives for the men and women of to-day, and cause us to pause and consider whither it is tending, and whether a short life and a merry one is after all more to be desired than the so-called old-fashioned slow lives of the days of our grandparents, when the moments were lived in a quiet content and deeply, not in a mad rush always to anticipate the future and to skim the surface in order to abolish any opportunity to reach the heart of life and its meanings. At least the medical examiner can now do his part by frankly telling his applicants what the inevitable result will be if the same unthinking life is continued.

Medical Section of the American Life Convention.—The third annual meeting of this Society will be held in St. Paul, Minn., on August 19, under the presidency of Dr. H. A. Baker. The program includes papers by V. M. Kime on "The Curve of Mortality," L. K. Frankel on "Popularizing Health Conservation," M. O. DeVeney on "Special Features of a Medical Director's Work," A. Talbot on "The Insurability of Women," and L. I. Dublin on "The Insurability of Women as Shown by Industrial Insurance."

Book Reviews.

Lehrbuch und Atlas der Konservierenden Zahnheilkunde. By Dr. Gustav Preiswerk. With 32 colored plates and 323 text pictures. Price 14 marks. München: J. H. Lehmann, 1912.

This text book for the use of practitioners and students is beautifully and profusely illustrated. It contains special reference to the operative methods employed in dentistry to-day. A detailed description of the steps in gold filling, and treatment of pulp and roots is given. This book is a supplement and finale to the three volumes recently published by the author. Stress is laid upon the technique and procedure of conservation.

Die Einfluss der Erwerbs und Arbeitsverhältnisse der Tabakarbeiter auf ihre Gesundheit. Von Dr. Thiele, in Oldenburg. Price 2.40 M. Berlin: August Hirschwald, 1913.

This little book opens with an account of the technique of manufacture of cigars, cigarettes, snuff, etc. The manufacture of the latter two and of chewing tobacco is mostly in cities, while cigars are made in the country. The conditions of home manufacture and also of child labor are discussed. The earnings are also set forth, followed by a description of the damage done and the means to combat it by improvements. Statistics of sickness follow, including anemia, nervous diseases and tuberculosis. There are many references to the literature and statistics of diseases and deaths in factory workers.

Diabetes: Its Pathological Physiology. By John J. R. MacLeod, M.B., Ch.B., D.P.H., Professor of Physiology, Western Reserve Univ., Cleveland, O.; late Dem. Phys., London Hosp. Price $3. London: Edw. Arnold; New York: Longmans, Green & Co., 1913.

This is a compilation of a series of eight lectures given in London University, 1912, and is intended to enable those who are unable experimentally to follow up the latest physiology and pathology to keep breast of the times. Examination for traces of sugar, sugar in the blood, and assimilation limits are well discussed. The latest work on the production of sugar from protein, possibly from fat, is given a chapter. The book is up-to-date and should be of use in every-day practice.

Festschrift für Herrn Professor Th. Kocher zur Feier seiner Vierzigjährigen Lehrtätigkeit von seinen Schülern gewidmet. *Deutsche Zeitschrift für Chirurgie*, 116 Band. Mit einem Bildnis, 120 Abbildungen im Text, 7 stereoskopischen Bildern in Mappe und 6 Tafeln. Leipzig: Verlag von F. C. W. Vogel, 1912.

That pleasant Teutonic practice of dedicating a special number of a medical journal to the honor of some famous professor finds an admirable expression in the "Festschrift für Kocher," which forms Band 116 of the *Deutsche Zeitschrift für Chirurgie*. This jubilee number marks the fortieth year of Prof. Kocher's pedagogical activities and contains a series of interesting and important papers written by his pupils and prefaced by an excellent halftone portrait of the master. As is quite natural, considering Kocher's life work, the subject of the surgery and pathology of the thyroid gland occupies a prominent portion of the text. There are two such papers on tuberculosis of the thyroid, an exceedingly rare condition, two on exophthalmic goiter, and one on the anatomical history of the thyroid gland, which abstracts some interesting old articles. An excellent article by Rollier, which is very well illustrated with *x*-ray photographs, details the results obtained in surgical conditions by heliotherapy. Space does not permit of a complete list of the papers, but among those particularly interesting and admirable are one on sporotrichosis, one on spontaneous fractures of the radius, with fifty illustrations, and an excellent article by de Quervain on the technique of thyroid operations, with twenty-three illustrations. The volume is therefore an important contribution to surgery and pathology.

Obstetric and Gynecologic Nursing. By Edward P. Davis, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College, Philadelphia. 12mo volume of 480 pages, fully illustrated. Fourth Edition. Thoroughly Revised. $1.75 net. Philadelphia and London: W. B. Saunders Company, 1913.

The fourth edition of Dr. Davis' well-known book has been enlarged and thoroughly revised in order to bring it up to date and it should prove of great value to those who are engaged in this branch of nursing. The book is well printed and clearly illustrated and serves as an excellent guide in obstetrical and gynecological nursing.

The Clinical Pathology of Syphilis and Parasyphilis. By Hugh Wausey Bayly, M.A., M.R.C.S., L.R.C.P., Pathologist to London Loch Hospitals, Clinical Pathologist to National Hospital for Paralyzed and Epileptic, Asst. in Bacteriological Dept. of St. George's Hospital. Price $2.25. New York: Wm. Wood and Co., 1912.

This book is intended for the general practitioner and student. It is designed to give the points of clinical pathology of syphilis and parasyphilis to aid in diagnosis and treatment. It begns with a study of *Spirochcta pallida*, its staining methods, culture, habitat, etc. Then follows a chapter upon blood changes, the anemia being most often of a chlorotic character. The Wassermann reaction is next discussed including technique, modifications, and clinical value. The antigen antibody phenomena are entered upon. Under treatment the technique of salvarsan treatment is described, also mercury treatment. The book is up to date and scientific.

Diseases of the Heart and Aorta. By Arthur Douglass Hirschfelder, M.D., Associate in Medicine, Johns Hopkins University. With an Introductory Note by Lewellys F. Barker, M.D., LL.D., Professor of Medicine, Johns Hopkins University, 344 Illustrations by the Author. Second Edition. Price $6.00. Philadelphia and London: J. B. Lippincott Company, 1913.

This very excellent work on diseases of the heart and aorta has in less than three years reached a second edition. As was said in a review of the first edition, the book is the outcome of the experience of a skilled clinician who is also well acquainted with the physiology and pathology of the subject, set forth in lucid and concise language. The book is well arranged and presented in a manner calculated to appeal forcibly to students and practitioners of medicine. Perhaps in no field of medical inquiry has more progress been made than in the study of the heart and its diseases. Mackenzie, Lewis, and Cushing have in some respects revolutionized our views with regard to certain aspects of heart movements and disease and further researches bid fair to change long standing ideas to a yet greater extent. As is pointed out in the preface to the edition, the electrocardiograph has thrown so much light upon the site of origin of the normal and abnormal heart beat, the action of the cardiac nerves, and the paroxysmal tachycardias and the permanent irregularity that it has become a procedure of routine in many medical clinics. This instrument is discussed in detail. Other investigations which concern the circulatory apparatus and which have been in progress since the publication of the first edition are dealt with adequately in the volume. A feature of the edition, as of the first edition, is the wealth of illustration; most of the figures, by the way, being made from original drawings and tracings. The book is a good specimen of the printer's and binder's art, and from a medical and scientific standpoint may be strongly recommended to the medical profession.

Handbook of Diseases of the Ear. By Richard Lake, F.R.C.S., England, Surgeon for Diseases of the Ear, etc. London School of Clinical Medicine, Surgeon to Seamen's Hospital and Royal Ear Hospital. Fourth Edition, revised and enlarged. Price $3. New York: Wm. Wood & Co., 1913.

The author states that this book is for students and practitioners though it seems somewhat comprehensive for the former. The anatomy of the ear is briefly discussed with several good illustrations: the general examination of the patient is next undertaken and covers history, past and present, as well as physical examination. Then follow descriptions of diseases of the external car (cysts, rodent ulcer, etc.) of external meatus (eczema, keratosis obturans, etc.) and of the middle ear acute and chronic, suppurative and nonsuppurative. The illustrations of various forms of caries are good. The intracranial complications of middle and internal ear diseases are given with their diagnosis. Operations are given some thirty-five pages including some good illustrations following which diseases of the internal ear are rather cursorily discussed.

Hydrologie Élémentaire. Par Allyre Chassevant, Professor of the Faculty of Medicine of Paris. Price 4 fr. Paris: Vigot Brothers, 1913.

This book has to deal with the pharmacology and therapeutics of mineral waters. The origin, composition, and physical properties as well as the chemistry and pharmacology of the mineral waters of France are discussed. There is a considerable study of geology and the movement of water beneath the earth, its filtration, contamination, etc. The contents of different waters are given, also their radioactivity. The book will probably be useful to those interested along these lines.

Die Prostitution, Vol. I. By Iwan Bloch, Specialist for Sexual Diseases in Berlin-Charlottenburg, author of "The Sexual Life of Our Times," "Origin of Syphilis," etc., etc. Price 10 mk. Berlin: Louis Marcus, 1912.

This book is one of great interest, and from the tremendous number of references in almost every language, is the result of almost endless labor. Prostitution is studied in every class, in every country and in every age, and though at times the psychology of the study seems somewhat Freudian, the book is calculated to hold one's attention to the end. Prostitution is described as a two-headed monster whose one face points to nature and the other to culture. It is a remains of the old free primitive sexual relation and its analogies are seen in monkeys. The earliest organized prostitution in history was at the time of Solon (630-560 B. C.) and it has come down through all the ages. A quite elaborate discussion is taken up of what constitutes prostitution and what the latter has meant in different countries and at different times. Almost all writers agree, however, that the greatest factors are publicity, gain in money, and repetition. Particularly Bloch emphasizes the lack of choice, that is, the generality as being characteristic, or, as he says, the "sine dilectu." He discusses conditions of free love and states that primitive marriage was probably of more economic importance than sexual. The forms of religious prostitution play a considerable part in history, for example, the prostitution before the temple of Aphrodite described by Herodotus. The old idea was usually that dancers and musicians were prostitutes, and Bloch describes many seductive dances used in this connection.

The organization of prostitutes is next discussed from the time of Solon and a classification is given.

Then follow chapters upon sexual perversions from earliest times, homosexuality, etc. The sexual question and its importance in the struggle against prostitution and the effect of Christian morals are discussed. The sexual ethics of Christian times have tended to cling to prostitution as a result of the double system of morals, and the chief organization dates from the thirteenth century.

The book has wide scope, and is scholarly without being heavy.

The Interpretation of Dreams. By Prof. Dr. Sigmund Freud, LL.D. Authorized Translation of Third Edition, with Introduction by A. A. Brill, Ph.B., M.D., Chief of the Neurological Department of the Bronx Hospital and Dispensary; Clinical Assistant in Neurology and Psychiatry, Columbia University; formerly Assistant Physician in the Central Islip State Hospital, and in the Clinic of Psychiatry, Zurich. Price $4 net. New York: The Macmillan Company, 1913.

The American medical public appreciates Freud as he is appreciated by no other medical public; and it is under obligations to the translator of this work for accomplishing a difficult task in making this masterpiece accessible to the English reader. In the plan of the book, the author gives in his first chapter a résumé of the scientific literature on the problem of the dream, from Aristotle down. In the second chapter he describes his method of dream interpretation and gives the analysis of a sample dream. The title of the third chapter is "The Dream Is the Fulfilment of a Wish." This is the central idea of the book. The fourth chapter is on distortion in dreams; the fifth on the materials and sources of dreams; the sixth, the dream-work; the seventh and last chapter is on the psychology of the dream activities. There is a literary index of 118 writings on dreams by other authors in the back. The book was written for the use of physicians and other scientific men and not for the reader looking for light reading. It will, however, undoubtedly be widely read; so, in view of certain recent modifications of Freud's infantile sex theory, there might, without loss, be omitted from future editions of the translation, a few of the cruder sexual interpretations used as illustrations. This also in view of the fact that there is really much of interest in the book for the general reader as well as the psychologist, neither of whom may have the broader conceptions of a medical training. The general index could be emended and added to with improvement. With these minor criticisms, the reviewer recommends unreservedly this book, as indispensable to the psychoanalyst and the psychiater and of distinct value to the physician; and of interest to all. It has not only a wide bearing on the study and treatment of certain nervous and mental disorders, but the new psychology therein expressed, is already revolutionizing the literature of these subjects and other literature and also our conception of art, ethics, and sociology. Freud's new psychology is beautifully worked out in a few of the more recent plays. The dream is intimately associated with both normal and abnormal mental life. In its relation to the psychoses it reveals to us, says the translator, in his preface, not only the cryptic mechanisms of hallucinations, delusions, phobias, obsessions, and other psychopathological conditions, but it is also the most potent instrument in their removal.

Medicolegal Examinations and the Workmen's Compensation Act, 1906. By Sir John Collie, M.D., J.P., Medical Examiner for the London County Council, Chief Medical Officer to the Metropolitan Water Board, Examiner (Accidents and Claims) Sun Insurance and other insurance offices. Price $2.00 net. New York: Wm. Wood & Co., 1913.

This book will be found of very practical interest to all who are brought into contact with workingmen, either as employers, insurance men, physicians, or lawyers as well as to legislators. It gives a very clear summary of the liability and compensation questions in Great Britain, but naturally much of its contents is applicable as well in America, especially in view of present and prospective legislation along the lines of workingmen's insurance, employers' liability, and compensation for occupational diseases. The following condensed table of contents will give a clear idea of the scope of the work and of its value in the way of suggestion to those interested in legislation along these lines: Psychological and Moral Effects of Legislation; The Detection of Fraud—Contracting Out; Summary of the Compensation Laws; Employers' Liability Act, 1880; Workmen's Compensation Act, 1897; Workmen's Compensation Act, 1906; Scope of the Act of 1906; Limitations of the Act; Amounts of Compensation Payable Under the Foregoing Acts—Compounding; Certain Diseases Scheduled as Accidents Under the Act of 1906; The Intention and Result of the Workmen's Compensation, 1906; Decisions of the Courts; Conclusions; The Remedy; Proposed Amendments of the Workmen's Compensation Act, 1906.

Insurance Medicine, being Suggestions to Medical Examiners. By Henry H. Schroeder, M.D.; Medical Director, Mutual Life Insurance Company of New York; Editor Insurance Department, Medical Record. Price $2.00 net. New York: William Wood & Company, 1913.

This volume is a collection of the articles which have appeared in the Medical Record during the past eighteen months under the title of "Suggestions to Medical Examiners." It presents and explains the attitude of the life insurance company in the matter of the examination of applicants for insurance and has for its purpose the establishment of a feeling of confidence between the field and home forces. It is written with tact, directness, and completeness, and seems well designed to accomplish its purpose. The position and experience of the author lend special weight to his words and the volume can be recommended without reserve to all who are interested in the subject.

The Individual in the Animal Kingdom. By Julian S. Huxley, B.A., Research Associate of the Rice Institute, Houston, Texas; late Lecturer of Balliol College, Oxford. Price 40 cents. New York: G. P. Putnam's Sons, 1912.

The author aims to give a general definition of the individual and to show in what ways individuality manifests itself in the animal kingdom. The major portion of the book is devoted to showing that living matter always tends to group itself into closed independent systems with harmonious parts. Such systems he believes to be identified with individuals. The book is intended to lessen the gap between science and philosophy and the ideas and interests of every day life.

The Soldier's Foot and the Military Shoe. A Handbook for Officers and Noncommissioned Officers of the Line. By Edward Lyman Munson, A.M., M.D.; Major, Medical Corps, United States Army; President Army Shoe Board; Director Field Service School for Medical Officers; The Army Service Schools, Fort Leavenworth, Kan. 54 Illustrations. Approved by the War Department. Price $1.35. Fort Leavenworth, Kan., 1912.

This very useful little book deals most thoroughly with foot injuries and marching capacity, the anatomy and use of the foot, the military shoe, the fitting of military shoes, shoe supply, the care of the feet, the socks, and the care of the shoes. Major Munson has given not only a valuable work on the care of the feet, but has rendered interesting a somewhat dry subject. The illustrations are excellent and the book may be commended to the consideration of civilians as well as soldiers.

Society Reports.

CONNECTICUT STATE MEDICAL SOCIETY.

One Hundred and Twenty-first Annual Meeting, Held in Hartford, May 21 and 22, 1913.

The Question of Balance.—Dr. Ansel G. Cook of Hartford said that in order to fit one successfully the surgeon had to think of 418 different things at the same time, and if he should forget one of them and it happened to be the most important—which it generally was—the other 417 would go for nothing. He observed that all of those things could not be thought of at the same time without system, and that that system was balance. Should a deformity exist in which the parts involved had become changed in shape he felt that the parts should be brought back into corrected position and used in that position until they became normal in contour. In deformity of the spine the parts should be put in a position so that the force of gravity would work for one instead of against one. In this way Wolff's Law would come into play and correct the deformity. Dr. Cook said that he had been able to accomplish this correction by means of a simple plaster corset, with windows in the sides.

Dr. Oliver T. Osborn of New Haven observed that there was no question but that orthopedists were needed, and that he thought the profession in general needed balance as well as the orthopedist. He said that the internist should state his findings and the orthopedist should state his; and that they should work together to correct the patient's condition.

Dr. William Porter, Jr., of Hartford agreed with Dr. Cook that the first thing to be done was to find out what was really the matter with the patient. He said that that principle applied to not only the orthopedist but to all members of the medical profession. He suggested that Dr. Cook's paper be read carefully by all of them and put into practice.

The Clinical Significance of Vertigo.—Dr. Charles A. McKendree of Cromwell expressed the opinion that vertigo included many degrees, from mere discomfort to manifestations of severe disturbance reported to consciousness from labyrinthian, ocular and static sources. He further said that it was very important to find out the exact nature of the sensation experienced by the patient; seasickness and train-sickness representing a vertigo in which the ocular and auditory nerves participated. He declared that vertigo from vascular degeneration was very common, and was often seen in organic brain disease. In lesions of the pons and cerebellum vertigo it should be regarded as an important symptom. He directed attention to vertigo in neurotic subjects, and said that no physician was justified in diagnosing a functional nervous disorder without first having eliminated every physical element and all the possible contributing factors.

Dr. Charles N. Haskell of Bridgeport thought that when the presence of brain tumor was suspected the first thing to be looked for was vertigo, and said that he had done a number of lumbar punctures without any ill results. He recommended that every one should be cognizant of the ordinary causes of vertigo, such as the reflex causes, like neurasthenia, epigastric ptosis, etc.

Dr. Henry L. Swain of New Haven felt that vertigo was an exceedingly interesting and contradictory sort of symptom, and an indication of many general diseases of the most varied types. He thought the objective symptom of vertigo, nystagmus, was most significant of the connection between the two important functions of sight and equilibrium, and said that marked vertigo, by the conditions inherent in arteriosclerosis, occurred with increased blood-pressure; the simple rotative test for ear-disease sometimes throwing to the floor a big strong man, whose blood-pressure was below normal. He stated that vertigo associated with a purulent middle-ear process was a matter of extreme importance and should be looked to carefully. If simple measures did not remove the danger signal, real surgery should be employed in order to avoid the danger of meningitis. He recommended small doses of quinine, with happily adjusted doses of bromide for working wonders in some forms of dizziness; and said that in others he used some preparation of ergot. In one case he had employed strychnine, in another pilocarpine, while in another strong glasses had removed all trouble. A simple case of a good calomel purge he also thought might be useful.

Dr. Frank K. Hallock of Cromwell declared that it was hardly possible to formulate a satisfactory anatomical basis for the production of all kinds of vertigo. In order to understand the clinical significance of vertigo he had divided the symptoms into the following varieties: First, the vertigoes which resulted from an organic or fundamental disturbance of the organs of the nervous system, which had directly to do with the act of equilibrium. Second, those, for example, secondary to blood and vascular conditions, were disordered functions, etc. Third, were those which were due to transitory physiological disturbances. Fourth, those which might be called psychic. Dr. Hallock stated that upon the particular state of the cortical centers, representing the basis of consciousness, depended the power of peripheral stimuli to cause vertigo.

Dr. Charles Fitzgerald of New Haven remarked that just now nystagmus was at the boiling point of interest to otologists. He thought that in chronic suppurative otitis media, if nystagmus was present the radical mastoid operation might suffice; but said that one must be prepared to perform the radical labyrinth operation later, if necessary.

Dr. Dorland Smith of Bridgeport said that one useful clinical fact was that if vertigo were aural in origin, nystagmus generally accompanied it, and if there was no nystagmus at the time of the operation the vertigo was not due to the ear.

Dr. E. Terry Smith of Hartford observed that vertigo was one of the most prominent symptoms that the oculist had to deal with. A slight paralysis of the extrinsic muscle of the eye, and a slight disturbance of the middle ear, which would disturb the pressure in the internal ear, were the two most frequent causes, he said.

Dr. McKendree, in closing, said that most men regarded lumbar puncture as a valuable adjunct to the treatment of persistent aural vertigo. He did not see the advantage of doing a radical mastoid operation before a labyrinthotomy. He differed from most men who thought that ocular vertigo was caused by errors in refraction, and held the opinion that it was produced by a paresis of a nerve supplying the ocular muscle.

The Work of the Infant Welfare Association of New Haven.—Dr. Joseph I. Linde of New Haven told of how the Pure Milk Committee had withdrawn from the Consumers' League in 1912 and formed the Infant Welfare Association. The old system of dispensing milk had been very expensive and had contained no educative value. All the mother had had to do was to give the babies the milk already prepared for them, but now, he said, they were putting the work on the mothers by teaching them to prepare the milk themselves, and that it had been wonderful to see how they had responded to the teaching. He stated that the Visiting Nurses' Association had supplied the nurses and four stations had been established. The nurse assigned to each station held weekly conferences with the mothers, who brought their babies to be weighed and examined by the doctor in charge. He said the formula was changed whenever it was thought necessary, and sick babies were referred back to their own physician. He described how the mother was taken into the laboratory and given a lesson in making modifications of milk on her first visit, and how, the next day, the nurse visited her at her home in order to see that this work was being done properly. Materials were supplied at cost, and when milk was delivered at the home the Association insisted that it be from a dairy whose name was indorsed by the New Haven Medical Society. By the end of the first summer pre-natal instruction was begun.

Dr. Julia E. Teele of New Haven felt that scientific philanthropy had regard to two things: the study of the conditions and the changes in them and the education of the people; and that preventive medicine and scientific philanthropy joined hands in infant welfare work. She considered the home-modification of the milk far superior to the standard formulæ, and said that, much to their own surprise, they had been able to teach most of the mothers—no matter how ignorant—to mix the milk properly and to care for the infants in a hygienic manner. She said that at their conferences on Monday they gave instruction in feeding the baby, general hygiene, the bathing of the baby, care of its clothing and also the care of the home. She had been much pleased that their work had kept up during the winter, and laid great stress on the importance of pre-natal work; recommending that the nurse should visit the prospective mother and give her advice as to the care of herself, the engaging of a doctor, going to a hospital and suggestions in regard to the coming baby.

Dr. Merriman Steele of New Haven said that he had, at the beginning of their work in New Haven, been absolutely convinced of the necessity of station-made modi-

fications, but he was glad to report that under the guidance of Miss Gilbert and her able assistants a clean milk had been made possible in a tenement; where the only thing clean was the milk and the utensils used in its preparation.

Dr. Kate C. Mead of Middletown stated that their nurses in Middletown were not trained, but practical; and that while they had been able to carry on their work for only three months during the summer, yet that had reduced the death rate one-half. She was concerned with the fact, however, that many of the babies saved during the summer had died in winter of pneumonia, because they could not afford to have nurses call and look after them during that time.

Dr. Frank W. Wright of New Haven thought that they had pretty well educated the milk producers and dealers, and that the one who needed education now was the mother of the infant.

Dr. Arthur S. Brackett of Bristol felt that it was neither necessary nor right that a few persons should stand the expense of all the work, and stated that the State should see to it that the schools were used as teaching centers; lectures along these lines being given in them at night. He also suggested the teaching of the young girls, from eight to twelve years of age—to care for the babies and expressed the opinion that they would take a live interest in the subject, as, next to the mothers, they had the most care of the infants.

Dr. Linde, in closing, stated that they had had some cases of pneumonia during the winter months among their station babies, but he did not know the exact number. He showed a pamphlet which they gave out that contained instructions as regarded the daily care of the bottles and which recommended breast-feeding, fresh air, etc.

The Treatment of Chronic Suppurative Lacrymal Disease.—Dr. E. Terry Smith of Hartford stated that Theobold was the first to treat lachrymal disease scientifically. To his mind the destruction of the canaliculus seemed poor surgery. He preferred the method of Mueller of Vienna, which was described in Fox's textbook. He showed some photographs taken after extirpation. In the first case the sac was removed without rupture, and the patient made an uninterrupted recovery. The second case was a double extirpation of the lacrymal sac. He declared that cases of acute and chronic dacrocystitis formerly constituted a legacy passed from one oculist to another, and seldom cured, many eyes being lost through ulcer of the cornea. He favored the treatment of these cases radically, unless there was some contraindications.

Dr. Dorland Smith, of Bridgeport stated that for some years he had been following a method devised by his partner, Dr. F. M. Wilson, which avoided the slitting of the canaliculus, and admitted of using quite large probes. In his description he said that the first step was to cut, with sharp-pointed scissors, from the punctum straight back to the edge of the eyelid, as far as the perpendicular part of the canaliculus went. He advised probing by all means, if the doctor and patient had the courage; but said that if either lacked the courage, to excise the sac.

Pseudoileus Due to Intestinal Nerve Impulse Disturbances.—Dr. Patrick J. Cassidy of Norwich said that enterospasm was a neurosis of the intestines associated with affections attending a general neurotic condition. The symptoms of the attack might vary from simple constipation with pain and distension to the grade of the most pronounced symptoms of complete metchanical obstruction. He advised operative interference as being a benefit from the point of diagnosis, and said that this would enable the physician to caution the patient as to the best means of preventing the frequency of future attacks. He felt that this disease should be given more thought, as the patients were increasing in number.

Dr. Joseph M. Flint of New Haven favored the operative treatment of cases of obstruction, because of the mimicry of pseudoileus to the true type. He thought that medical men were more liable to see such patients than those in hospitals. He had had two cases; one, high in the ileum; the other, in the transverse colon.

Dr. Oliver C. Smith of Hartford felt that the question of intestinal obstruction was one of as great importance to the general practitioner as to the surgeon. He said that in three thousand laparotomies the only cases in which they had found pseudo adynamic ileus had been explicable on some general anatomical grounds. He thought that there was a tendency on the part of the physician to err on the side of conservatism in cases of intestinal obstruction, and said that he, himself, had postponed operations too long.

Dr. John W. Churchman of New Haven reported having seen in one patient the actual lesion. During operation the small intestine became completely obstructed by a sharp and definite localized spasm of the ileum, causing a tumor mass, which could be picked up and handled. It made the diagnosis absolutely positive. A cure was brought about by the administration of large doses of belladonna.

Dr. Ernest H. Arnold of New Haven said that he constantly met with spasms of the stomach in tubercular lesions of the dorsal region of the spine. He advised, in cases of repeated attacks, in which the operation failed to relieve the condition, that the spine be subjected to a careful *x*-ray inspection.

Dr. Cassidy, in closing, stated that he wanted to emphasize the necessity for early operative interference in all cases presenting the symptoms of intestinal obstruction. The medical treatment he advised was belladonna and opium.

Aniline Dyes in Surgery.—Dr. John W. Churchman of New Haven felt that the principle of selective affinity which some drugs had for the cells of the body was really an old one. The recognition of what that principle meant had had two general effects; first, by increasing the ability to recognize cases, and, second, by increasing the ability to treat them. Among the drugs that had this selective action he mentioned lead, quinine, mercury, salvarsan, etc. He told how fifteen years ago he had shown that it was possible to demonstrate a selective affinity between a common dye, gentian violet, and certain bacteria. By use of that dye one could pick out distinctly two kinds of organisms—one absolutely unaffected by the dye; and the other, killed, if stained with it, and prevented from growing if gentian violet were added to the media in which they were growing. He asserted that in poliomyelitis the dye had a distinct restraining effect on the virus; but he was not willing to claim that it actually killed it. He was confident that eventually something important would come out of the findings in that line.

Dr. Leo F. Rettger of New Haven told of how methylene blues had been regarded as a particularly active agent, and were known as far back as 1880. He claimed that their results had borne out those of Dr. Churchman and stated that all those dyes had a wonderful fusibility throughout the body, and if the extreme disinfection action could be combined with that quality there was great hope in the treatment of all bacterial infections.

Prolapse of the Uterus.—Dr. Otto G. Ramsay of New Haven stated that the one constant factor at work in all such conditions was the change from the normal relationship of the pelvic floor. As a result of that the vaginal walls separate and roll out when there is any exertion on the part of the patient. The pelvic tissues should be brought back to their proper relations as nearly as possible, he said; and failure in operating was due to a wrong conception of the etiology and development of the condition. In the young he advised the classical operation; but in the older patients he suggest another kind of operation. He reported 75 of such cases with no mortality; his oldest cases being three years old, with no recurrence.

Dr. Phineas H. Ingalls of Hartford declared that prolapsus uteri had been a bugbear to surgeons for years. He felt that the sliding down of the bladder and the rolling out of the anterior rectal wall caused a great deal of trouble; but the idea of stitching the round ligaments to the apex of the triangle was new to him. He cautioned against long operations in these cases, and felt that an operation on these organs, which did not include the taking back of the cystocele and the rectocele would be a failure.

The Present Status of the Röntgen Rays in Diagnosis (with Moving Pictures).—Dr. Arthur C. Heublein of Hartford showed some very fine *x*-ray moving pictures of the gastrointestinal tract with a bismuth meal; and declared that the scepticism which had long prevailed concerning the accuracy of Röntgen rays in the diagnosis of bone injuries, etc., was fast disappearing. He said that in the lower urethral region it was absolutely necessary for the cystoscopist and the radiographer to work together. It was his opinion that gallstones were seldom found by means of the *x-ray*, because of their being largely made up of organic salts.

Dr. Thos. N. Hepburn of Hartford told of how he had worked with Dr. Heublein in the field of renal diagnosis, and how they had, with the aid of the *x*-ray and collargol injections of the ureter discovered that urethral disease was comparatively common, and had been previously frequently overlooked. He described their method of getting collargol injections—which varied from most persons. They used a dilating catheter and inserted it into the urethral part until it fitted snugly, and then let the collargol flow in, using the gravity method. Anywhere along

the course of the ureter one might see the stricture in the fluid column. Dr. Hepburn also advocated *x*-ray as a help in deciding what to do with the kidney; and he emphasized the importance of taking *x*-ray pictures of both kidneys for renal calculus, as double renal calculus was exceedingly common. He advised that the surgeon also have a picture after the operation in order to prove that the calculi were not there.

Dr. Orrin R. Witter of Hartford declared that Dr. Heublein's demonstration more fully demonstrated the value of the *x*-ray in diagnosis than any written article could have done. He wished to emphasize the value of a negative finding in the case of a kidney condition in which the entire clinical picture was of renal calculus with extreme pain and blood in the urine, the *x*-ray picture being negative.

Dr. George Blumer of New Haven had occasionally found that chronic interstitial nephritis was accompanied with typical attacks of renal colic, and felt that in such cases a negative picture would be of great value.

Dr. Heublein said in closing that he always made it a point to go over both kidney regions, the ureters and the bladder.

Pyelitis.—Dr. Charles J. Bartlett of New Haven stated that pyelitis was common in both adults and children, and was one of the easiest conditions to pass unrecognized; being frequently overlooked or mistaken for some other disease. He said that in acute pyelitis the destruction of the tissues was slight, but in the later stages the organ was usually beyond repair; the urine being bactericidal and quite resistant to bacterial invasion under normal conditions. He felt that the most common predisposing cause was some anatomical condition interfering with the outflow of the urine, the intestinal wall becoming impervious to bacteria, under certain pathological conditions, and allowing the bacteria to enter the blood-stream. He advocated, as a rational treatment, the use of hexamethylenamine; increasing the quantity of the dose until free formaldehyde was formed in the urine, thus producing the toxic effect. When vaccines were used he said that they should be autogenous.

Acute Primary Pyelitis in Children.—Dr. Fritz C. Hyde of Greenwich believed it was possible that mild cases of pyelitis often recovered without especial treatment, and that the infection was usually ascending; giving the following reason for his belief: Infection, via the female urethra from soiling of the vulva was theoretically easy and likely, whereas infection borne by the blood would probably cause involvement of the true kidney structure and not localize in the pelvis of the kidney. Recorded cases showed no evidence of nephritis, he said. His six cases, all girls, were characterized in common by fever, pus in an acid urine, no bladder symptoms—except in one instance—and prompt improvement and cure by the use of ordinary antiseptics.

Dr. John W. Churchman of New Haven felt that cases called bacteriuria were impossible to distinguish from cases called pyelitis. There was no question whatever in his mind but what organisms could easily reach the pelvis of the kidney from the blood-stream. He thought the success of internal medication depended on two things, namely, the character of the invading organisms and the extent to which the organisms had invaded the tissues, and if the invasion had been made into the substance of the kidney that they would be very hard to dislodge. In cases of pyelitis in pregnancy he advised the administration of urotropin during the puerperium.

Dr. Charles A. Goodrich of Hartford said that many pyelitis cases had been first treated for malaria, while others had been mistaken for digestive derangements. He had not had much success with potassium citrate, but felt that urotropin, in moderate doses, was beneficial.

Dr. Geo. Blumer of New Haven thought that the type of pyelitis not recognized in adults was that described as primary pyelitis, often occurring in connection with pregnancy and sometimes with menstruation in non-pregnant women. He said the temperature charts in pyelitis and in some cases of pneumonia were very much alike and advised routine examination in every case of that disease.

Dr. Bartlett, in closing, spoke of Vanderhoff's claim that this condition might be recognized at diagnosis in two per cent. of the cases, provided the examination was well made.

Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis.—Dr. David R. Lyman of Wallingford observed that if the lungs could be put to rest in such cases the chances of recovery on the part of the patient were greatly increased. He felt that that procedure would also promote the formation of connective tissues and tend to limit the process and finally control it. He preferred the use of nitrogen gas to either oxygen or sterile air, and the incision to the puncture method of performing the operation, although he admitted that recent improvement in the puncture method seemed to have made it the one of choice. It was his belief that injury to the lung and the production of gas emboli might be avoided by means of the manometer.

Dr. H. S. Wagner of Hartford remarked that during recent years there had developed a tendency to study the failures and to report on them and to let the successes take care of themselves. He felt that this was particularly true with regard to the treatment of pulmonary tuberculosis by means of pneumothorax, and declared that such a procedure meant real advance. He believed that pneumothorax would decrease the räles and sputum in certain tubercular cases.

Dr. Henry F. Stoll of Hartford also advocated the use of the manometer, saying it was the only thing to do, for if you had an adhesion you could not strike the pleural cavity and the hole would be much larger. He used holocaine, instead of novocaine, with good results, and said that if you waited a few minutes after injecting the holocaine, before operating, you would have complete anesthesia. He used an aspirating needle of fair size with a comparatively short point.

Dr. Lyman, in closing, stated that when discomfort came he always stopped, and he thought it would be risky to do a deep pneumothorax in such cases.

Officers.—The following officers were elected for the ensuing year: *President*, Dr. D. Chester Brown, of Danbury; *Vice-Presidents*, Dr. W. M. Hurlbert, of Stamford, and Dr. Kate C. Mead of Middletown; *Secretary*, Dr. M. M. Scarborough of New Haven; *Treasurer*, Dr. Joseph H. Townsend of New Haven. The next annual meeting will be held in New Haven May 20, 1914.

AMERICAN NEUROLOGICAL ASSOCIATION.

Thirty-ninth Annual Meeting, Held in Washington, D. C., May 5 to 7, 1913.

The President, Dr. Pearce Bailey of New York, in the Chair.

Presidential Address.—Dr. Pearce Bailey of New York delivered this address, stating that in all organic life there existed two principles for action, viz., desire and fear; desire showing itself as a tendency on the part of the individual to acquire for himself what was beneficial, and fear a tendency to avoid, by whatever means possible, what was harmful. There soon became associated with these two motives the emotions of pleasure and pain. As evolution proceeded these two motives became enormously elaborated to form instincts, and through all the instincts one or both of them could be found. With the development of the intelligence the instincts became very much checked and modified, so that desire showed a constructive purpose and fear became sunk in the unconscious, showing itself chiefly as prudence. Human personality was a combination of the instincts with fear and desire back of them, modified by the checks of the intelligence, but the fundamental motives could always be detected, and man, however much his primal characteristics might be hidden by the teachings of his intelligence, nevertheless remained essentially an egotistic individual. This could be shown by analysis, in his ordinary actions, and became very evident under any circumstances which acompanied an unhinging, temporary or permanent, of his intellect. Thus, under the stress of violent emotions, of fatigue, of physical disease, and especially of mental disease, the teachings of the intelligence were more or less lost sight of, and a man reverted or regressed to earlier types of behavior. Under these circumstances he showed various phases of the evolutionary stages through which the race had passed.

The Present Status of Neosalvarsan in the Treatment of Parasyphilis of the Nervous System.—Dr. Edward D. Fisher of New York read this paper, stating that since the finding of the spirochetes in the brain and cerebrospinal fluid in general paresis and tabes the term parasyphilis must be discontinued. All diseases of the nervous system due to syphilis were due to the same active agent which was the cause of the pathological changes, both in cerebrospinal syphilis and in the more chronic manifestations formerly classed under the head of parasyphilis. The discovery of the spirochetes gave us a rational basis for the use of neosalvarsan. The question arose: What was the relative efficiency of this remedy in the later manifestations of syphilis of the nervous system, i. e. in tabes and general paresis? In the writer's experience the hopes raised by Prof. Ehrlich's discovery had not been

fully realized and could not be. We had only to consider the pathological changes in these diseases to understand the reason why. We had, however, with the Wassermann reaction test a rational plan of treatment in the use of neosalvarsan and mercury and the iodides. As we found the Wassermann test negative we could stop our medication and resume it as it became again positive. It was certainly rational to remove the active agent of disease, as we could by the use of neosalvarsan, and thus prevent further extension of disease. In the light of our present knowledge we were in a position to make an early diagnosis, and the importance of beginning treatment early was emphasized. The importance of being conservative in our claims for this most valuable remedy should be emphasized, as it must be many years before we could know whether its early employment, i. e., at the time of the initial lesion, prevents the later manifestations of syphilis of the nervous system.

Dr. Joseph Collins of New York said that he was in accord with Dr. Fisher in regard to the necessity of now and forevermore dispensing with the terms parasyphilis and metasyphilis. He was not sure that we all recognized a fact which seemed to be a fact, namely, that when face to face with tabes and general paresis and what was known under the term of meningeal syphilis, we were not dealing with nervous disease, but dealing with the disease syphilis. Dr. Collins said that he had understood Dr. Fisher to say that the spirochetes were found in the cerebrospinal fluid. Dr. Collins supposed they had never been found in the cerebrospinal fluid.

Dr. Philip Coombs Knapp of Boston stated that the clinical and pathological distinction thus far justified the division into ordinary syphilis and parasyphilis and that it was a convenient distinction which he thought might still be held. In regard to the use of neosalvarsan and salvarsan Dr. Knapp's experience had been that there was a good deal still in Ehrlich's original claim that in syphilis of the nervous system the results were not so likely to be beneficial as in the early stages of syphilis manifesting itself in other organs of the body. Experience both with neosalvarsan and salvarsan in syphilis of the nervous system had not, on the whole, led Dr. Knapp to believe that we had gotten so much more than we had in the use of mercury and iodine. In the last two months he had been trying the intraneural method and thus far the benefits of the method seemed to be uncertain and possibly not of sufficient value to warrant the increase of danger that accompanied the use of that method.

Report of a Case of Juvenile Tabes.—Dr. C. Eugene Riggs of St. Paul, Minn., presented this paper, saying that a boy of 7½ years, with no luetic history in either parent, no symptoms of hereditary syphilis, had begun to have gastric crises when ten months old; they now occurred every there months. Marked ataxic gait, muscular weakness, knee and Achilles jerks were absent. The blood exhibited a positive Wassermann and spinal fluid the same; no lymphocytosis, no globulin excess.

Dr. Philip Coombs Knapp of Boston stated that cases of juvenile tabes were so rare that it seemed to him permissible to speak of a case now in his wards, which, although not confirmed by autopsy, seemed to him probably a case of juvenile tabes, a girl of 16 of whom nothing could be learned in regard to her family history. At the age of 5 she had been run over and her head injured, suffering several scalp wounds and being unconscious for a day. After that there had been no trouble at all until the age of 11, when her sight began to fail. At the age of 12 she had lost vision completely. Some one examined the eyes and found the optic atrophy of so-called traumatic origin. There had been a history for 1 or 2 years of typical tabetic pains, sharp, shooting pains of brief duration. On examination there was some perception of light and well marked primary atrophy of both disks, no indications of any keratitis, no radiating scars about the lips. The two central upper incisors were peculiar, in that they were somewhat broad, but there was no characteristic of Hutchinson's. The knee jerks were absent on one side, obtained only by reinforcement on the other. There was marked Wassermann in the blood and the cerebrospinal fluid and globulin reaction, but no increased lymphocytosis.

Dr. H. M. Thomas of Baltimore said that a boy of 7 years was sent to the Surgical Department of Johns Hopkins with the diagnosis of tumor, probably of the cerebellum. Dr. Thomas was asked to see the lad in consultation. He had been extremely bright up to the fifth year, when he had begun to deteriorate and then it was thought that he had an injury. His deterioration took the form of being unable to speak as well as he had before; he had been loquacious; he became noisy and fretful and hard to manage and his walk became so unsteady that he could hardly get about. On examination he showed no signs of hereditary syphilis. He had no choked disk, his walk was distinctly cerebellar, his pupils were distinctly unequal, they did not react to light, and his reflexes were exaggerated. The boy's blood gave the positive Wassermann reaction and the diagnosis of cerebral syphilis was made. He was given two doses of neosalvarsan and changed markedly. He became quieter, his walk became steadier, and he left the hospital, having done pretty well. However, on getting home he became extremely quiet and in a week he was brought back in an absolutely different condition. At that time he was speechless, his walk was perhaps a little less ataxic, still he made no attempt to walk. The physical signs were the same. A lumbar puncture was done. He had a cell count of 33, positive globulin and positive Wassermann, and a Wassermann in his serum was also positive. The case then seemed to be one of juvenile general paresis and as it was the only case the consultants did not venture to make that diagnosis, yet they had been extremely interested.

Two Cases of Removal of Extradural Tumor of the Spinal Cord.—Dr. Philip Coombs Knapp of Boston read this paper, saying that tumors of the spinal cord were rare. In 3517 autopsies at the Boston City Hospital a tumor was found only four times, but the spinal cord was not always spared. In 1294 patients in the neurological service a tumor was diagnosticated 10 times. In 11 cases operation had been performed, in 6 cases with fatal results, in 4 with some improvement, so that the patient could get about on crutches, and in the fifth with marked improvement followed by a return of symptoms and a second operation. Two of these cases were reported. Case I. Woman, 40, married, nullipara. Menopause at 36. Considerable alcohol. Entered hospital May 20, 1912. For six months or more had had pain between the shoulders, shooting into arms, and worse on motion. For three or four months the pain had been growing worse, for six weeks the legs had been numb and for two weeks paretic. Micturition was difficult and the urine at times had to be drawn. Sexual desire unimpaired. Some rigidity of dorsal spine. Legs paretic and spastic. Knee jerks exaggerated, double Babinski. Sensibility diminished from level of ensiform cartilage downward. Unable to pass urine which contained a trace of albumin and some pus. Wassermann and Noguchi in blood, positive. The cerebrospinal fluid was clear, 20 lymphocytes to a cubic millimeter, globulin reaction absent. Wassermann and Noguchi negative. Somewhat vague shadow in upper dorsal region. The paresis increased to complete paralysis, the spasticity was much greater. Salvarsan and mercury did not benefit her. July 30 laminectomy by Dr. E. H. Nichols. Two small masses were removed from external posterior surface of dura at level of sixth dorsal spine. Made a good surgical recovery. She gradually improved, regaining control of her bladder, being able to stand alone and walk with crutches, and having normal sensibility. She was still somewhat spastic and had exaggerated reflexes. She was still on crutches and in the hospital for chronic diseases. Case II. Woman, 33, married, four children. Entered hospital July 30, 1912. Three years before, in the sixth month of her fourth pregnancy began to have pain in the right loin, buttock, and leg. After delivery the legs grew weak. Pain subsequently appeared in left leg. Loss of sexual desire, micturition and defecation imperative, occasionally incontinent. Gradual increase in weakness of legs. When first seen was unable to stand or walk without support. Sensation diminished below a line 22 inches below umbilicus. Tender over lower dorsal vertebrae. Some spasticity. Wassermann and Noguchi negative. Lymphocytes twenty to a cubic millimeter. Laminectomy August 16 by Dr. J. A. Hubbard. Small growth, apparently fatty, removed from posterior external surface of dura at level of eleventh dorsal spine. Dura opened, arachnoid bulged, no pulsation. Considerable fluid drained from arachnoid. Some fever and bedsore, but otherwise she made a good surgical recovery. Gradual recovery of motion and sensation. Able to stand and take a few steps on September 7. Toward the end of October walked without crutches, and later improved so that she could walk half a mile, dance, and travel in the trolley cars alone. Early in January, 1913, she took cold, and her symptoms gradually returned, so that early in February she returned to the hospital in much the same condition as in the previous July, but the hypaesthesia extended to 2 inches above the umbilicus. There was a good deal of pain in the back and the legs were weak and spastic. March 15 the wound was reopened by Dr. Hubbard and the spinous process above was removed. No adhesions were found, but the cord was tense and did not pulsate. The dura was opened and much cerebrospinal

fluid escaped. She made a good recovery and was discharged April 21. There was then a very slight hypaesthesia with some allocheiria in the right leg. The right leg was somewhat hypertonic, but she had good strength in both legs and could walk with crutches or with very slight support. The operations that had been done in Boston, fourteen of which had been already reported, had been collected, and showed the following results: Tumor removed 8, 6 improved, 2 died; tumor partly removed 7, 3 improved, 4 died; tumor found, not removed, 4, 2 improved, 2 died; lesion found, not tumor, 6, 3 improved, 3 died; nothing found 6, 3 improved, 2 died, 1 result uncertain. Shersberg collected 119 operations; of these 49 were benefited, 42 died.

A Peculiar and Undescribed Disease of the Nerves of the Cauda Equina.—Drs. Foster Kennedy and Charles A. Elsberg of New York said that during the last first years, in a large number of spinal operations, 84 of which were performed by one of the writers, they had met with five cases so alike in their histories, their clinical findings, and in the peculiar swelling and discoloration of the root of the cauda equina that they have been led to class them together in the belief that they form a definite clinical and pathological entity. Pain was present in the back of the thighs and legs in all of the patients; atrophy of the anterior muscles with loss of the power of dorsal flexion of the foot was present in 4; the objective sensory changes consisted of loss in the sacral and lowest lumbar nerves. The disorganization of the functions of the bladder and rectum was complete in 4 paticnts. The abdominal reflexes were regularly present, while the ankle jerks were lost in 4; the knee jerks became lost coincident with the upward progress of the disease. The conditions found at operation were mainly a swelling and reddish-blue discoloration of many or all of the roots of the cauda equina. A thorough search of the literature failed to reveal any proven cases like those described. A few cases had been reported in which a clinical diagnosis of neuritis of the cauda equina was made and the condition believed to be syphilitic, but in none of these was the diagnosis verified by operation or autopsy. A very similar disease has been described in the horse, and in these animals the post-mortem examination revealed a condition very like that found in the patients operated upon and reported in the paper. The Wassermann test both in the blood and cerebrospinal fluid was negative in all of the cases, therefore the condition is not luetic. Nor were there any signs of a meningeal lesion.

Giant Tumors of the Conus and Cauda Equina.—Drs. Joseph Collins and Charles A. Elsberg of New York presented this paper. They said that the patient began to complain of pain and stiffness in the back extending down the posterior aspect of one and then of the other thigh. The pain was intermittent at first, later it was continuous. After the expiration of one year or more the symptoms became worse, one or double drop foot appeared, the lower limbs became weaker and stiffer, knee and ankle jerks disappeared. Then followed difficulties in the functions of the bladder and rectum, irregular sensory loss, rigidity of the lumbar vertebral column, tenderness of the lumbar spines. Peroneal palsies were regularly found with electrical changes. The patients were often suspected of tabes, and had usually been treated for long periods for sciatica. The important features of the clinical histories were the following: A history of one or more years' duration, pain in the small of the back sooner or later extending down one and then the other extremity; stiffness of the back in the lumbar region; increasing weakness and stiffness of the lower extremities with loss of power of dorsal flexion of the foot; slight disturbances of the bladder and rectum. The important features of the clinical examination were the following: Rigidity of the lumbar vertebral column; weakness and stiffness of the lower limbs; paralysis of the peroneal groups of muscles and sometimes of the tibialis anticus group; dropped foot on one or both sides; absence of knee and ankle jerks; tenderness of the lower lumbar spines; irregular and unsymmetrical sensory disturbances; lumbar puncture usually negative. The typical findings at operation consisted of a large reddish-brown not vascular tumor within the dura, which filled up the entire lower part of the spinal canal, surrounded the roots of the cauda equina and extended upward on the conus with which it was not closely connected. The growth was not intimately connected with the inner surface of the dura, and could be easily freed from it, after which the inner surface of the dura was found to be smooth and glistening. The growths were well encapsulated above, but were closely connected with the nerve roots below. The peculiar features of the tumors were: Their large size; the late appearance of bladder and rectal disturbances; the relatively small amount of sensory loss in spite of the fact that the tumors fill up the entire lower part of the spinal canal; the benign course of the disease, without tendency to perforate the dura. Operative interference should be done in two stages by the "extrusion" method. If the cases were recognized early, radical removal of the growths should be possible.

The above three papers were discussed jointly.

Dr. Archibald Church of Chicago said that he was reminded by Dr. Knapp's paper of an experience of comparatively recent date, which, while it might not be edifying, might be interesting: that was, the recurrence of three tumors followed by three successful operations in the same patient. The first tumor made its appearance four years ago. At the end of a year the patient was entirely paraplegic. Dr. Patrick saw the case in consultation. Dr. Murphy operated. A tumor was removed from the cervical region. She made an uneventful recovery and in the course of six months recovered. At the end of two years she began to have the same symptoms of spinal tumor and within six months had developed the same symptoms. A second operation found another growth in connection with the pia about an inch lower than the first tumor. Whether this was a recurrence of the first growth was not known. It was supposed to be essentially an independent neoplasm. For nine months she had comparative freedom. Two weeks ago she came back to Chicago for recurrence. Early last week a third operation was done and a third tumor removed. So there was one on the right, one on the front, and one on the left. Dr. Church said he had had two cases of cauda equina. Some eight years ago a surgical friend had the typical manifestations of caudal lesion. This endotheliomatous growth filled the entire neural cavity and was supposed to be so intimately related to the cord that no attempt was made to remove it. The man perished from kidney trouble. About three years ago Dr. Church saw a young boy with terrible pains in the legs who had been treated for hysteria. After many months of observation he showed a little area of sensory loss corresponding to the cauda and upon this comparatively slight symptom, although the bladder was not materially affected, an operation was done and an infiltrating endotheliomatous neoplasm extending from the middle of the lumbar spine to the lower end of the sacral canal was uncovered. It was not considered feasible to remove it and safest to let the case take its course. The operation wound has remained perfectly solid. The symptoms have not increased, but a tremendous growth had invaded the abdomen so that he looked like a six-months pregnancy. Apparently the pressure had been relieved from the caudal region so that further neural symptoms were inhibited and the growth had gone in the anterior direction. This large caudal involvement may be more frequent than we suppose.

Dr. W. M. Leszynsky of New York stated that in regard to the difficulty of diagnosis in tumors of the cauda equina and inflammation of the roots, the mere fact that one can obtain no cerobrospinal fluid should lead one to make the differential diagnosis between the two conditions.

Dr. William G. Spiller of Philadelphia stated that this subject of the root neuritis confined to the lower portion of the cord was one of great interest. One could not help wondering whether in that case there was a meningitis of a certain degree, possibly of a considerable degree, and whether the root changes were not part of this meningitis. Dr. Elsberg stsated that the cord showed nothing to the naked eye. There might have been marked meningitis which would not have been detected by naked eye at all. Tumors varied very greatly as to whether they were in the upper part of the cord or in the lower. In the upper they were more of the type of fibroma and endothelioma, well defined tumors that might be readily removed in most cases. In the lower part of the cord they were very much more malignant, infiltrating, liable to be greater in size and offering much more unfavorable conditions for removal. In one case of inoperable tumor operated on for me by Dr. Edward Martin he cut the anterolateral columns to remove the pain. It was very successful. The patient lived two years after that operation. He died a few months ago, with an enormous tumor filling a large part of the abdomen.

Dr. Joseph Collins of New York said that it seemed to him so far as the patient's restoration to a degree of health and usefulness was concerned that operation on these caudal tumors as they were now being done did not give any considerable degree of life and did not restore them to any degree of health. The significance of this fact was that we must diagnosticate these cases earlier than we do now. If we relied upon the presence or absence of the cerebrospinal fluid in a case

that had the symptoms of caudal tumor in making the differential diagnosis we would go wrong very frequently. Dr. Collins made a plea for operation on caudal tumors in every instance at the time when suspicion entered the mind that these were present, and, second, for operation in tumors of the conus five, six, eight, ten years before the time they are now operated on.

A Contribution to the Pathology of Myasthenia Gravis.—Drs. SIDNEY KUH and MORRIS BRAUDE of Chicago presented this paper. They said that theirs was a typical case of myasthenia gravis in a physician 50 years of age, of a duration of about five years. Examination of the nervous system was made with the Weigert myelin sheath stain and Pal's modification of the same, Mallory's chloride of iron hematoxylin, Ford-Robertson's toluidin blue, thionin, Nissl's methylene blue, toluidin blue counterstained with erythrosin, uranium carmin, Van Giesen's stain, Weigert's fibrin stain and the same author's stain for elastic fibres were used on about 400 sections. Small areas of vascular sclerosis, recent (agonal?) hemorrhage, increase in glia tissue, corpora amylacea were found in the spinal cord. In the cervical region there was an aberrant bundle of fibres. In the higher levels of the cord capillary polymorphonuclear thrombi and chromatolysoc and pigmentary changes were seen in the nerve cells. The relative intensity of these latter findings remained approximately constant, i. e., where the thrombi were numerous the changes in the nerve cells were greater. The same applied to medulla and corpora quadrigemina. In the cortex there was but little of these changes to be seen; more in the optic thalami. The muscles showed nothing that had not previously been described. There was no trace of the thymus found.

Bilateral Oculomotorius Palsy from Softening in Each Oculomotorius Nucleus.—Dr. WILLIAM G. SPILLER of Philadelphia read this paper saying that bilateral oculomotorius palsy developing in an apoplectic attack, syphilitic in origin, implicating every muscle supplied by the oculomotorius in each eye, resulting from bilateral softening as two separate lesions confined to the nuclei of these nerves; without implication of other cranial nerves except the opticus, and without other symptoms except preceding mental disturbance, convulsions and some change in the patellar reflexes and succeeding extension of each big toe from plantar irritation were the chief features in the case reported in this paper. The author discussed the several symptom-complexes resulting from vascular occlusions he had studied, viz.: The occlusions of the posterior inferior cerebellar artery, of the uppermost portion of the anterior spinal and adjoining portion of the vertebral arteries, of the cervical anterior median spinal artery, of the vessels supplying the inner segment of each lenticular nucleus, and (in the case reported in this paper) of occlusion of the vessels to the oculomotorius nuclei. In the last mentioned condition there were symmetrical softening and paralysis of all branches of the oculomotorius, although the paralysis may not be complete in all the muscles innervated by the nerve; there were also involuntary incoördinate movements and great rigidity with unconsciousness at the onset of the attack.

Lesions of the Hypophysis and of the Uncinate Region, with the Records, Clinical and Pathological, of a Series of Cases.—Drs. CHARLES K. MILLS and WILLIAMS B. CADWALADER of Philadelphia presented this paper. The paper was based on a series of eight cases, two of which had been previously shown at another society, both before operation. Of the eight cases one had presented uncinate without pituitary symptoms, necropsy in that case showing a large tumor involving the uncinate convolution, but extending into other regions of the cortex and subcortex. Of the other seven cases three presented both pituitary and uncinate phenomena of a decided character. In the other four uncinate symptoms were absent, pituitary phenomena being pronounced. These phenomena, however, were of a mixed character, illustrating dyspituitarism rather than either hypo- or hyperpituitarism. In one of the cases with decided uncinate symptoms no lesion of the temporal lobe was discoverable. In one case, in which the patient died after operation, a necropsy showed a tumor involving the fundibulum and pineal gland adjoining structures. In three of the operated cases pathological conditions of the hypophysis were found at the operation and confirmed by microscopical examinations of parts of the tissue removed. The authors are favorable to the frontooperation of Dr. Frazier for the exposure of the hypophysis. They believe it has distinct advantages over that of approach by the nasal route. Only operation, however, gave successful results in a limited number of cases. The authors of the paper discussed the manner of the production of the conjoint pituitary-uncinate symptom-complex.

Dr. J. RAMSAY HUNT of New York asked whether Dr. Cushing had any cases of complete transitory blindness referred to him. Dr. Hunt said he had had quite recently, with Dr. Kinnicutt at the Presbyterian Hospital, a case of pituitary disease in which there were no changes in the sella turcica. The man was placed on extract for two or three weeks. He returned to the hospital saying that he had been seized quite suddenly in the engine room, where he was working, with blindness which had lasted for four hours at the time Dr. Hunt saw him. It seemed that the blindness had something to do with the acromegalic signs.

Dr. HARVEY CUSHING of Boston, in reply to Dr. Hunt's query, said that he had seen many cases of scotomata, and these scotomata, as de Schweinitz had pointed out, were very apt to occur in the upper outer quadrant. They were largely due to the fact that there was apt to be fluctuation of these symptoms. The gland swells against the chiasm which accounts for the loss of vision in the upper and outer quadrant. In cases which had passed beyond the stage to be cured by operation he would limit himself to a minor measure, such as the mere relief of pressure, rather than a large major operation, such as the exposure of these structures through the frontal region. Such a lesion as a cyst was, of course, easily approached from below. The duration of the stay of the patient in the hospital from operation by the transsphenoidal route is comparatively a few days. It is not much more than submucous resection of the septum, which the laryngologist not infrequently practices in the Out-Patient Department. There have been 104 patients in his series and there have been 75 surgical cases. In 46 of the 75 there had been the transsphenoidal operation; in 22 subtemporal decompression and eight have had transsphenoidal and temporal decompressions. So that there have been 93 operations. There have been nine fatalities, about 10 per cent. Most of these fatalities occurred in the early series. Thus of these fatalities most of them were cases which to-day we would recognize as inoperable or would adopt a simple measure. Two of them were simple subtemporal decompressions with very large tumors. He thought the operation merely took part of the growth. It was inconceivable that one could remove the entire growth. If the growth was accessible from below he thought it should be approached from below. What we want to do is to make room for enlargement of the growth. We could not remove it entirely. He felt that this measure to which Dr. Frazier had again called attention, and which was first advocated by Hartley and subsequently by Krause, was in Dr. Frazier's skilful hands a measure that very likely could often do good, but it was one which Dr. Cushing said he would feel very badly to have come into general use.

Huntington's Chorea: A Study in Heredity.—Drs. SMITH ELY JELLIFFE, ELIZABETH B. MUNCEY, and C. B. DAVENPORT of New York presented this paper. In the last ten or twelve years they had been able to get together enough information to show that one could group these cases of Huntington's chorea into four large groups. For the last four years Dr. Muncey has spent all the time working on this material, with the result that practically of the old family Huntington chorea in this country has come from five distinct families. The names of these families are now fairly well known. It has taken thirteen years to collect the material and it will take five or ten years more to present complete analyses of what the material shows. At the present time it confirms the statement frequently made that Huntington's chorea does not skip a generation. If any individual is free from the disease that individual's offspring will be free. Once the line of descent is free, always free. If one individual does not have the disease it means that he does not have it in his germ cells and hence cannot transmit it. The practical application of this rule to eugenics was diminished by the fact that Huntington's chorea does not come on until late in life. As to marrying, each member feels that he may escape and, if he considers the matter at all, runs the chance. In a person whose onset is relatively late in life it is to be expected that the parents will often die before the disease was due to develop in them. In certain of the families one would find the cropping out of the Huntington chorea, nothing in the antecedent heredity, and later it turns out that there was illegitimacy, so that occasionally comes into these charts to explain the law of Mendelian dominance.

The Perimetric Deviations Accompanying Pituitary Lesions.—Dr. HARVEY CUSHING of Boston read this paper stating that in a series of 104 examples of pituitary

disease, the greater number accompanied by manifestations of tumor, due either to an enlargement of the hypophysis itself or to a superimposed lesion, changes in the fields of vision have been present in a large proportion of the cases. Few physicians at the present time venture to make a diagnosis of an hypophyseal lesion in the absence of a bitemporal hemianopsia; and it has been Dr. Cushing's experience that the majority of the neurologists and ophthalmologists through whose hands these patients have passed have hesitated to make such a diagnosis—although there were obvious deviations from the normal in the perimetric outlines—for the reason that these deviations did not show the characteristic bitemporal defect with a more or less definitely vertical meridian separating blind from seeing fields. As a matter of fact, in a considerable number of these cases the field defect has been an homonymous one; for when the enlarging gland bursts through its dural capsule it may extend into the interpeduncular space to one side of the chiasm rather than in a median posterior position. The opportunity has been given in this series of cases, not only in many instances to follow the progressive changes in the visual fields as the defect advances, but also to follow the steps by which the normal peripheries become restored after a transsphenoidal operation when partial removal of the growth has afforded relief from pressure. These experiences have shown that in the majority of instances the defect advances in very characteristic fashion, usually beginning in the upper and outer temporal field and affecting color vision before vision for form. These minor changes are as typical of a retrochiasmal lesion as is the full-blown textbook picture of complete bitemporal hemianopsia. Furthermore the defect rarely advances with equal steps in the two eyes, and consequently for each individual eye it proves to be a matter of clinical convenience to divide the advancing process into stages, as follows: Stage I shows merely a notch, often quadrantal, in the upper temporal field for color, though there may be in addition some slanting off of the form field. This is due to the fact that the ventral crossed fasciculus is affected by the pressure at an earlier stage than is the dorsal crossed fasciculus, the transmission of color impulses suffering earlier than the transmission of form impulses. Stage II.—In this stage a beginning quadrantal constriction in the form field follows upon the quadrantal defect for colors. Stage III.—Here color vision is more or less completely lost in the entire temporal field, the form constriction remaining practically quadrantal, with beginning encroachment upon the lower temporal field. Stage IV.—In this stage hemianopsia is complete for form and colors, the macula still being spared by the otherwise practically vertical meridian. Stage V.—Hemianopsia remains complete for form and color, the macula now being included in the vertical meridian, there being in this stage often an actual complete macular blindness for colors. Stage VI.—Macular vision is lost for form as well as colors and the nasal field begins to shrink from the vertical meridian. Stage VII.—Color vision is entirely lost and a patch of vision for large objects remains, usually in the lower nasal quadrant. Stage VIII.—Blindness. The least affected eye progresses in the meantime along the same route; for it cannot be emphasized too strongly that the process rarely advances with equal steps in the two eyes. Indeed, commonly enough one eye may be completely blind, whereas the other may show a condition in Stage I, or indeed with no observable change whatsoever. Even after Stage VIII with blindness has been reached some vision may be regained by operative measures, which goes to show that the disturbance is brought about not only by an anatomical destruction of the fibers through a process of degeneration but also by a physiological block to the transmission of impulses superimposed on the actual atrophic changes. Though the prospect of a return of vision therefore is not utterly hopeless, even when blindness has supervened, it is nevertheless of great importance for us to recognize these evidences of chiasmal pressure in their early stages. Pituitary disease, as I must continue to emphasize, is a common malady, heretofore largely overlooked. One serious complication of the disorder is a so-called primary optic atrophy, and this is in many respects the most obvious of the neighborhood symptoms and one for which surgical measures are as definitely indicated as when dyspnea is produced by pressure against the trachea in cases of goitrous enlargement of the thyroid gland.

Tuesday, May 6—Second Day.

General Palsies Without Demonstrable Anatomical Findings.—Dr. John H. W. Rhein of Philadelphia read this paper. He said that cases of cerebral palsies without demonstrable lesion in the brain and without implication of the pyramidal tracts had been frequently reported. These palsies were usually of toxic origin, such as occur in nephritis, tuberculosis, lead poisoning, puerperal infection, and alcoholism. There was also a group of cases of hemiplegia without disease of the pyramidal tract in which was found in the basal ganglion a lesion consisting of lacunæ. There were besides these a large group of cases described as infantile cerebral palsy. In a number of these cases no true degeneration was found in the pyramidal tract but a fineness of the fiber, a scarcity of fiber, incomplete myelization, imperfect development of the pyramidal tracts or atrophy of the pyramidal tracts is found. What was the cause of the paralysis in the three cases Dr. Rhein reported of this type had been undetermined. Whether it was due to some deficiency of nerve cell which baffled present methods of study, to faulty connection between various layers of the cortical cells, whether the nerve fibers in the pyramidal tract had not developed in sufficient numbers in the lower levels of the cord, or whether the fineness of the fibers interfered with this perfect function by offering undue resistance to the transmission of the motor impulse from the cortex and thus preventing the full motor discharge to reach the periphery was still a matter for study in the future to determine.

The Value of X-Ray Analysis of the Gastrointestinal Tract in Some Types of So-Called Functional Nervous Disorders.—Drs. L. Pierce Clark and Archibald H. Busby of New York presented this paper. They said that in a careful and complete *x*-ray analysis of eight cases of idiopathic epilepsy associated with severe gastrointestinal disorder the authors found some form of abnormal position of the viscera (ptosis) which they judged to be pathological in each case and which they connected up with some of the clinical symptoms in the individual case. They outlined a system of physical therapeutics to overcome the gastrointestinal ptosis which had been of functional benefit. They advised a routine *x*-ray examination in every case of genuine epilepsy with severe indigestion as an aid in exact diagnosis and treatment of the indigestion and the convulsive disorder itself.

Dr. D. J. McCarthy of Philadelphia said that he could support what Dr. Clark had said in his paper from an extensive study of the past year on not only this group of cases, but the entire group of functional cases that come to the neurologist's office. Wherever there had been any suspicion of gastrointestinal involvement, he had *x*-ray tests made. The percentage of cases of what had been considered the purely functional neuroses in which one gets lesions not only equal to those shown in Dr. Clark's group of cases, but even more intense, was surprising. Among those cases operated on, where they had been well selected, uniformly excellent results had been obtained.

Dr. Herman H. Hoppe of Cincinnati said that he believed that, while the study of this condition was very interesting, before the profession could come to any conclusion as to the therapeutic results a larger number of cases must be studied. There was, on the part of a great many patients, an objection to having an operation of a serious character done for a primary condition that had existed for a long time. Some practitioners have found the straight front corset to answer nearly all purposes. One case of epilepsy occurred to him as presenting complete recovery following operation.

Dr. J. W. McConnell of Philadelphia said that he was not interested in the surgical side of these cases, believing, as he did, that the matter of internal therapeutics had not been sufficiently worked out. There was too much tendency to go ahead and carve up these patients. For several years he had been working very carefully at the condition of displacement of the abdominal organs with direct reference to their effect upon the nervous system and incidentally upon the general digestion. In the matter of treatment of these cases he had largely been depending upon abdominal supports made of very heavy adhesive plaster. Up to the present time he had certainly 300 or more cases in which there had been very distinct relief of the gastrointestinal symptoms and a very definite improvement of the peculiar toxic condition which those patients naturally get into.

Dr. C. A. L. Reed of Cincinnati said that he had had a number of these cases referred to him, notably by Dr. Hoppe and Dr. Langdon, and he had had some very satisfactory results following surgical restoration of these displacements. It was no more possible to reduce these displacements by medicines than it was to reduce a dislocated elbow with a dose of pills. He had not infre-

quently applied bandages, trusses, and so on with benefit, temporary or partial. But that that treatment can by any possibility restore the patient to normal condition was something not for a moment believable.

Dr. Edward B. Angell of Rochester, N. Y., said that as soon as you have corrected the intestinal fermentation that distends the bowel and causes the pressure permanent relief will be afforded the patient. He has many times had the pleasure of taking off the supports and leaving the patient much more comfortable.

Wednesday, May 7—Third Day.

Dr. Philip Zenner, Cincinnati, First Vice-President, in the Chair.

The Interpretation of Differences in Mammalian Brain Weight in Terms of the Structural Elements.—Dr. Henry H. Donaldson of Philadelphia read this paper. He said that among the different species of mammals of increasing size and increasing brain weight, present information justified the general conclusion that the larger brains were composed of the greater number of structural elements. Within a given species, however, the question arose whether the number of elements in the large brain was really greater than in the small brain, or whether we were to regard the large brain as composed of the same number of structural elements as the small brain—the size of the elements accounting for the difference in gross size. In man we found differences of 10 to 20 per cent. in the brain weights among the two sexes and at different ages after maturity. There was about the same range of difference in brain weight in the rat—the brain of the very large, wild Norway being about 20 per cent. heavier than that of the corresponding domesticated albino. Using the rat as the species for study, the following relations have been found: The brain weight was alike in the two forms (wild Norway and albino) during the first three weeks of life. The relative weights of the divisions of the brain are alike in the two forms, despite the difference in absolute weight. The percentages of water in the several subdivisions are similar in both forms. The observed number of medullated fibers in one peripheral nerve (nervus peroneus) is the same in both forms. The size of the cell bodies in several localities was found to be greater in the Norway than the albino. Finally, as the weight of the brain was closely correlated with the body size, it was possible to produce from the same litter by modifications of diet animals with brains of different absolute sizes. These brains presumptively contain the same number of neuroses. All this points to the general conclusion that in the case of the rat the differences in the size of the brain are due to differences in the size of the elements. If we apply these tests to man, we find that so far as the observations exist the results are similar. It was concluded, therefore, that within a given species of mammals—illustrated by man and the rat—the difference in the absolute weight of the brain either within the same sex, or when the two sexes are compared, was mainly due to differences in the size of the constituent elements.

Dr. E. E. Southard of Boston said that as to the question of agenesia versus aplasia connected with the dementia præcox brains which he had been studying he found that the various persons with whom he had talked felt that, for instance, in a small brain in dementia præcox patients there might well be agenesia. If these conclusions of Dr. Donaldson were correct, it might be that the small brain of dementia præcox, like the small heart or small aorta, was an instance of aplasia or hypoplasia rather than agenesia. Agenesia should mean a condition in which certain elements are lacking; while aplasia should mean an alteration in the negative direction, in the size or other qualities of the cells. There were no gradations in respect to agenesia: it was either genesis or agenesis. We should be careful how we speak of the brains as examples of agenesia. If we get used to employing the word agenesia, we will come to think that dementia præcox means an absence of certain elements; whereas, it may not at all mean such. In fact, the evidence would seem to the speaker to be rather that the dementia præcox brains were in possession, perhaps, of their normal quantity of elements. Many counts would have to be made to make this point good.

Dr. Henry H. Donaldson of Philadelphia said he had recently been over a short series of brains belonging to deficient and defective children from the Vineland (N. J.) Institution; and, separating them into their larger divisions of cerebral hemisphere involvement, etc., and taking the weights of these he was rather surprised to find that the weight relations were those of the normal brains, in most cases. His own interpretation, in fact, was in favor of the view that the elements composing these brains were small in size, rather than deficient in number.

Experimental Study of Intraneural Injections of Alcohol.—Dr. Alfred Gordon of Philadelphia read this paper. He said that the experiments were carried out on dogs with the object of determining the effect of alcohol on motor and sensory or mixed nerves. The facial, infra-orbital, and sciatic nerves were exposed by dissection during anesthetization with chloroform and 5 mm. of 80 per cent. alcohol were injected. The first series of dogs were kept alive nine days, the second series 29 days. Not only the periphery nerve-trunks, but also the nuclei (Gasserian and spinal) were examined microscopically. The facial nerve was traced through its course in the medulla. The histological and clinical findings were then given in detail. The conclusion to which the author arrived was that while very little or no damage was done to a motor nerve, the sensory and mixed nerves presented very little resistance to the effect of alcohol. Irreparable damage might be done in the latter case, but in the case of motor nerves restoration of function was almost the rule. Illustrations of the histological findings were appended.

Dr. Israel Strauss of New York said that he could in a way bear witness in confirmation of the author's results. Two years ago he saw a patient into whose sciatic nerve there had been an injection of alcohol, the result of which injection was a complete paralysis of the muscles of the leg. This paralysis lasted over one year; and, in addition to said paralysis, there developed trophic ulcers upon the foot, also a marked edema. There was at the end of a year almost no sign of restoration of the power of those muscles and the trophic ulcers, while they would heal, would appear in new regions. It was his opinion that probably the trophic condition of the foot put that patient in such jeopardy that amputation might eventually be necessary.

Dr. Edward B. Angell of Rochester, N. Y., asked Dr. Gordon whether he had examined the sciatic nerve after the injection of a saline, rather than alcohol. This would be rather interesting because such injections are now made by men who are using injections for the relief of neuralgias.

Dr. Peter Bassoe of Chicago said he considered it his rather painful duty to tell about an experience with an injection in a case of sciatica—not with alcohol—but with salt solution, a method which he had used a good deal, and which he was still using. In the summer of 1908 he injected a number of cases at the Cook County Hospital of Chicago, and a number of cases were injected by the internes, both in the speaker's service and in that of his colleagues. There was one typical case of sciatica injected by an interne; and within, say, half a minute, or at most within one minute, a complete sciatic paralysis was produced. The needle was introduced through the buttocks rather high up, using the landmarks advised by some French writers and drawing the line from the conjunction of the coccyx and sacrum over to the upper border of the trochanter. The patient was a nervous man; he did not like the feeling of the needle and jumped. Possibly that had something to do with it, but at any rate the paralysis and loss of sensation were instantaneous. I at once examined him and found there was complete paralysis of all the muscles below the knee and loss of all forms of sensation. The man's sciatica was cured and never returned. The patient still has a complete paralysis of those muscles.

Dr. Alfred Gordon, answering Dr. Angell's question regarding personal experience in injecting saline solution, said that he had had quite a number of cases that had been relieved, but not cured, by physiological salt solution. He had tried in two cases the injection of plain distilled water and had obtained equal results as with the saline solution. He had never observed such a danger as Dr. Bassoe had mentioned from injecting saline solution into the sciatic nerve.

The Rôle Which Heredity Plays in Inducing Epilepsy in Children Suffering from Infantile Palsy.—Dr. L. Pierce Clark of New York and Dr. Edward A. Sharp of Buffalo, N. Y., presented this paper. They stated that in a comparative analysis of some 886 cases of epilepsy, divided equally between those suffering from the idiopathic disease and hemiplegic epilepsy, the authors found that the heredity charts of the two classes were practically identical quantitatively and qualitatively. They therefore deduced the conclusions that the prognosis in any cerebral

hemiplegic child predisposed to epilepsy because of his palsy was enormously increased by the presence of a hereditary neuropathic constitution in a given case, and that the palsy *per se* played a secondary role and a much less important one than heretofore supposed.

Dr. E. E. Southard of Boston said that at the Psychopathic Hospital the chief of the out-patient department, Dr. Lucas, had been working upon heredity in epilepsy, and an interesting confirmation of Dr. Clark's conclusions was in process of being obtained. The worker had spent eight months upon the heredity in these cases, and had unfortunately been unable to establish what the speaker and his associates thought she might establish, namely, the difference in the heredity features in the organic and inorganic cases. Dr. Southard said that he would judge that an intensive work upon this small number of cases would entirely confirm Dr. Clark's results.

The Feeble-Minded in Massachusetts Outside of Institutions.—Dr. William Noyes of Boston read this paper. He stated that this inquiry was undertaken under the direction of the State Board of Insanity, which had the duty of recommending to the Legislature the provision that should be made each year for the institutional care of the feeble-minded. Heretofore no data have existed that would give an adequate idea of the extent of the provision needed because of the varying estimates of the number requiring institutional care. All the available sources of information were utilized and the data received were entered on cards, one for each individual. The cards were finally brought together in alphabetical order to prevent duplication, showing a listing of 5,007 individuals, 2,640 males and 2,367 females, who were considered by one or more persons as being feeble-minded. These totals do not include returns from the schools of the five large cities of Boston, Cambridge, Lowell, Fall River, and Salem. It is estimated that there are at least 628 institution cases in the schools of Boston. It is easily seen, therefore, that the institution cases in the schools of the four other cities would increase the totals in a very marked degree. On the other hand, it must not be assumed that the 5,007 individuals listed in the census are by any means all institution cases. Defective delinquents have been rejected when known to be such. For the purpose of comparison with the State census of 1905 a more intensive study of a given section, including 21 towns, was made; 105 feeble-minded individuals were found, while the State census gave but 37, a very marked difference. If the same proportion held throughout the State, the total number in the community would be 7,861. A committee has prepared tables estimating the cost to the State of three feeble-minded families—the W—— family and two branches of the B—— family. The tables are made on the estimated cost of caring for a feeble-minded child by the State Board of Charity at $180 a year until the average age of 33. The totals of these feeble-minded children are as follows: 9 members of the W—— family will cost the State $30,705; 7 members of the B——I family will cost the State $21,470; 3 members of the B——II family will cost the State $12,600.

Dr. L. Pierce Clark of New York considered the census which Dr. Noyes had made as highly important from many points of view. He was rather surprised to find from Dr. Noyes that the number of feeble-minded in Massachusetts was relatively small. In New York City alone there were over 7,000 uncared-for in the schools, even at a conservative estimate, without a definite census being made. In New York the profession had doubts as to whether the special classes for instruction could serve other than as a makeshift until segregation in colonies could be undertaken. It was the best thing that offered itself.

Dr. William Noyes of Boston said that segregation with them meant merely committing the subjects to the schools at Waverly and Wrentham, State institutions. Of 87 women under the charge of the State Board of Adult Poor, 68 were known to have had children—92 illegitimate and 17 legitimate, making a total of 109 children borne by 68 feeble-minded and borderline mothers. The statistics did not, as a rule, include the borderline cases because for various reasons authorities would not report a case unless pretty well marked. Dr. Noyes believes that all States having to deal with this problem will have to come to this, that there shall be a definite census made of them and of those the profession would look on as more dangerous, and that the State shall assume charge of all these and say they cannot have their liberty.

Dr. Dana of New York stated that the latest estimate of New York State had something like about 5,000 of this class, and so it seemed to him the estimates mentioned by Dr. Noyes rather confirmed the estimates made in New York.

Dr. Noyes said in conclusion that he was surprised and gratified when the inquiry into these special towns came out that it practically agreed with what was generally put out, about 1 in 500. He obtained the data himself in the summertime.

Lesions of the Hypophysis from the Viewpoint of the Surgeon.—Dr. Charles H. Frazier of Philadelphia read this paper, in which he presented four cases of hypophyseal disease in which the hypophysis had been approached by his transfrontal intracranial method. There were no operative fatalities. He called attention to the advantages of this over the transsphenoidal method, as indicated by his own experience and from a review of sixty-five operations by various surgeons who had used the extracranial approach. He called attention to the difficulty in determining before the operation what the nature or size of the lesion was. The same clinical picture would be present in all sorts of hypophyseal lesions, including hyperplasia, benign and malignant growths. Any one of these lesions might lead to evidences of hypo- or hyperpituitarism or to neither. The only evidence of pituitary disorder in many cases was revealed in the visual disturbances and the signs of intracranial tension without the least suggestion of the perversion of the metabolic processes. The confusion that had arisen in the minds of the experimentalist as to how vital the hypophysis was for the maintenance of life was called attention to, and Dr. Frazier was inclined to accept the opinion of those who had found in animals that complete removal was not incompatible with life. He referred to the further confusion in the minds of the pathologists as to the classification of pituitary tumors, and showed how comparatively benignant was the life history of certain malignant lesions, so that in the presence of malignancy the beneficial effects of operation would extend over a number of years. The author reviewed the indications for surgical therapy, the beneficial results of which were seen in the majority of instances in the relief of the visual disturbances, headache, psychic disorders, and to a less extent of the symptoms of acromegaly and dystrophy. He found it of advantage in his own cases to combine glandular feeding with surgical intervention and did not believe that operation should be resorted to, except in the presence of impending blindness, until glandular feeding had been given a trial. He was quite fully convinced that in the future the transfrontal method of approach would be adopted by the general surgeon, and, if the transsphenoidal method were used at all, it would be practised only by the specialist trained in the technique of intranasal procedure. Palliative procedures, such as temporal or sella decompression, were only of questionable value and only transitory in their influence upon the symptoms.

Dr. Cramer said that in 1911 there had been brought to him a patient who, in 1873, had become completely blind. This, of course, was before the days of pituitary agitation or much pituitary knowledge. In 1911 she appeared with the pituitary syndrome and died with inanition in the latter part of that year. Here was a patient who lived with pituitary tumor, blind, from 1873 until 1911. If operation could not influence or retard the development of compression symptoms, it made no difference how safe the operation might be, whereas, if the intracranial route would do this to a greater extent because, as Dr. Frazier had pointed out, the tumor most frequently grows upward, that operation would be the one that should be developed.

Dr. Alfred Reginald Allen of Philadelphia said that in the past year Dr. Frazier had sent him four specimens of scrapings or excisions from a part of the pituitary. The point of interest was the discrepancy of opinion of various men as to what these growths were. He had been greatly interested in the peculiarity of the process simply from a morphological standpoint, and whereas, the profession had a very complete idea, from the histological and histopathological aspect, of chronic interstitial nephritis, and many other things of that kind, yet when we came to the pituitary our knowledge was very slight. The speaker believed that one reason for knowing so little was that the surgeon would dig out a piece in the operating room and set it aside, and the piece would remain until after the operation, and in the meantime dry out and thus reach the pathologist's hands in bad condition for study. If surgeons would care better for these tissues we would soon know a great deal more about the histopathology of neoplasms of the pituitary body.

Dr. Herman H. Hoppe of Cincinnati said that he had in his possession a brain tumor that had been obtained before the days of the *x*-ray, and also before the days of

much knowledge of hypophyses. It was a hard fibroma, that was probably two inches in diameter. It never could have been removed by the transnasal route. To-day this case would have been diagnosed at once, and could have been removed very easily by the transfrontal route. This man's life would have been saved, absolutely, providing the surgical technique had been successful.

Dr. Charles H. Frazier of Philadelphia stated that in his paper he had tried merely to state the problem from the standpoint of the pathological features with which surgeons had to deal in order to open the way to some conclusion as to the best method of dealing with this problem. He had tried to be conservative, at least in his estimates of the usefulness and the limitations of surgery. The point he wished to emphasize, however, was that these so-called malignant lesions do run a very benign course, and when these tumors are large in proportion they grow up toward the hemispheres and not down, so that they were more readily approached from above; also that in most of the operations done through the endonasal methods, there had been a very incomplete removal of what in many instances was a very large tumor, and, lastly, that, in the hands of most surgeons discussing general surgical procedure, the intracranial method would prove to be the safer of the two. When one recalled to mind the anatomical features of these two operations, it would be observed that one could draw a line from the tip of the nose, or one approximately from the upper lip back through the sphenoid processes to the sella turcica, which line would be longer than a similar line through the supraorbital ridge to the sella turcica. If in the early stage of the operation, one would puncture the dura over the frontal lobe, so that during the subsequent stages the cerebrospinal fluid was allowed to escape as freely as it would in order to afford an opportunity for the displacement of the hemisphere from that portion, if one displaced the frontal lobe upward, with the patient's head in the so-called Rose position, if then, one had a suitable headlight, which in some instances is necessary and in some not, according to the character of the day, a very correct view could be had down to the optic foramen, or down to the point where the optic nerve passed through the optic foramen. It was not necessary to remove the rim of the foramen. When you were at the apex of the orbit you were really within a trifling distance of the pituitary body, and it remained then only to make a transverse or horizontal incision in the dura about a quarter of an inch above the floor of the base of the skull in order to avoid the sinus, it remained only to make this horizontal incision in the dura to expose the contents of the sella turcica. As thus described, this sounded like a very simple procedure, which it was. In most instances it was more simple than the exposure and removal of the Gasserian ganglion, this not because he was partial to the operation, but he thought there were other surgeons who had tried the method who would confirm what he had said. The speaker had had a conversation last night with Dr. Elsberg of New York, who had done the operation only once, and had been really surprised at the comparative simplicity of it and at the facility with which he had reached the sella turcica and exposed a large round growth, and subsequently removed it with most striking results. The matter was still subject to question and we could not come to any definite conclusion on one side or the other, but the speaker still felt that eventually we would find that, if the pituitary body be approached, and, if the lesions of the pituitary proved to be amenable to surgical therapy, the transfrontal approach would be the more desirable of the two.

Election of Officers.—The following officers were elected for the ensuing year: *President,* Dr. Henry Hun of Albany, N. Y.; *Secretary-Treasurer,* Dr. Alfred Reginald Allen of Philadelphia, Pa.

Case of Ossification in the Brachialis Anticus.—E. M. Corner reports the case of a young man who fell on his hand a few months ago, fracturing the lower end of his radius. There was no complaint of any injury or pain in the neighborhood of the elbow-joint. Later the patient discovered a painless lump in front of the elbow. A skiagram showed that this lump was due to some ossification in the brachialis anticus muscle. Presumably this was the result of a partial rupture of the muscle, done unconsciously at the same accident.—*Proceedings of the Royal Society of Medicine.*

Books Received.

The Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

IS APPENDICITIS EVER CATARRHAL?

By FRANK A. PALMER, M.D.,

MORRIS, ILL.

The caption, catarrhal appendicitis, is one which is found in all classifications of disease of the appendix and is used to designate clinically those cases which show only slight but long-continued or persistently recurrent symptoms. Clinically the meaning of this term is clear and may suffice, but when the cases come to be classified upon the basis of the pathology present we find the widest divergences of opinion and description, each author using the title, feeling called upon to explain just what he means in a pathological sense by the heading, and these explanations run a certain gamut of meaning or uncertainty of meaning, which varies directly with the familiarity of the writer with the microscopical pictures which occur in the sections of appendices removed at the operating table. Those with the least familiarity of the kind describe the most typical picture and are more nearly at one as to the nature of the conditions described, while, strangely enough, those who have made a special study of this complicated little corner of microscopical pathology are much less concise in their description of catarrhal appendicitis and vary most among themselves in regard to the physical appearances which occur in this form of inflammation. All of this leads one to suspect that there is something wrong with the caption and that there is perhaps something of a handicap imposed thereby in the preconceived ideas which the classification involves.

Of the older descriptions of catarrhal appendicitis the following is perhaps a fair average example, being contained in the "American Text Book of Surgery," second edition, page 742. The italics are mine. *"If we could see such an appendix* we would undoubtedly find swelling and congestion, hypersecretion, nerve irritation. It seems theoretically unreasonable to suppose that in every such case there is necrosis of epithelium, or infection even of low grade. It is probable, however, that there is even in the mildest cases an exudate under pressure in the submucous and muscular coats of the wall of the appendix and a slight adhesive peritonitis of very moderate extent." The above is followed by a description of a moderate attack of appendicitis under the heading of "the usual symptoms of such a case as we are considering." This is frankly theoretical and is plainly an attempt to carry over to the appendix by analogy a type of catarrhal inflammation which is very definite and of very familiar aspect in other organs. It was chosen for citation here because it accurately expresses what we would expect to find in an appendix which we had already made up our minds was the seat of a catarrhal inflammation and because I believe it very closely approximates the picture of a mild and inoccuous type of inflammation which all of us hold up before our mind's eye when in the presence of a mild case of appendicitis. And lastly, it is cited here because this is the picture toward which all the less informed writers tend in their description of the pathology of catarrhal appendicitis, their description varying the more widely from it, the more extensive their actual observation of sectioned appendices.

Those who have studied these appearances extensively under the microscope and have then attempted to make the pathological phenomena, which they have actually observed, correspond to the classification and phraseology which they inherited from the older writers, have found themselves put to some difficulty, as is evinced by the two following quotations, to which I shall limit myself: The first is from Wm. C. McCarty (*J. A. M. A.*, Vol. IV, p. 488) who, perhaps, has done more extensive microscopical investigation of the appendix than any other American observer. He says: "To the pathologist the classification of the conditions found is similar to that made for the surgeon, but includes the acute catarrhal condition, which is rarely if ever seen in the strictest sense. It is difficult to obtain a specimen in which the term acute catarrh can be correctly used unless the term be extended beyond its real meaning and be allowed to include the extension of the process in the mucosa to the underlying submucosa, lymph follicles, and even through the lymphatics to the subserosa. The extension of the condition is so rapid when the process in the mucosa is acute that it is difficult to conceive of its being confined to the mucosa, as the name signifies. It may be well, however, since the name has become so well established in our nomenclature, to continue its usage with the modification that although the process has its origin in the mucosa, the submucosa and follicles share very early in the reaction." All of this would constitute a wide modification indeed from the accepted type of a catarrhal inflammation. Any severe inflammation of the appendix originating in the mucosa would come within the sphere of this definition. A little further along he says: "Appendicitis catarrhalis chronica arises as a result of repeated mild and severe acute catarrhal conditions and is marked by an increase of scar tissue and distortion of the normal regularity of the coats and glands." All of this is an evident attempt to fit the findings to a preconceived classification, rather than making a classification to fit the findings.

Note the differences in the following quotation based on the microscopical study of a series embracing two thousand cases, reported by Moschcowitz and Moschcowitz from the Mt. Sinai Hospital

in New York (*Archiv f. klin. Chir.*, Vol. 82, p. 683): "The appendix is usually flaccid; the surface is more or less reddened; in more than one-half of the cases adhesions are present with the parietal peritoneum or the surrounding organs. The individual layers are thickened; the mucosa is more or less hyperemic, and the lymph follicles are swollen. The lumen contains mucus or muco-pus, or, perhaps, feces. Frequently fecal concretions are found." They speak also of catarrhal appendicitis *with abscess!*

Evidently these two observers are speaking of entirely different groups of pathological phenomena under the same name in their efforts to make their findings fit an erroneous classification. I think these quotations will serve to bring forcibly to the attention the confusion which obtains in the classification of the lesser forms of appendiceal inflammation and the urgent need of a classification which will lead our observers less astray. Also these considerations serve to rouse the suspicion that the clinical cases which we call catarrhal appendicitis, and in which we picture to ourselves an appendix affected by a comparatively harmless inflammation of the mucous coat, may be affected by some other form of inflammation which is not so innocent. To answer these questions and quiet these surmises I took the appendices of eight cases of chronic appendicitis, who had never had an acute attack, but from whom the appendices had been removed for long-continued tenderness, or recurrent slight attacks of pain. No one of these cases had ever been sick in bed a day from their appendices. Each of these were sectioned extensively. In all nearly three thousand sections were examined. In no one of these appendices did I find a condition which could in any proper sense be designated a catarrhal appendicitis. In every case the findings plainly spelled out a past or present purulent inflammation, differing in no way except in degree from the severe inflammations of the appendix, which we hold in such wholesome respect. And practically every appendix contained conditions which subjected the patient to grave danger of being the victim of a severe purulent inflammation in the future. Two cases showed healed perforations of the appendix. One showed a perforation in which the healing process was not yet complete. Another showed a peculiar and interesting condition which could be interpreted only as the result of an abscess having formed in the appendiceal wall, with a final emptying of its contents, which fortunately ruptured into the lumen of that organ instead of into the peritoneal cavity. A detailed study of the various cases is appended at the close of the article together with microphotographs of the more interesting conditions.

Let me emphasize two points. First, none of these cases, all of which were picked because the symptomatology would most certainly classify them as chronic catarrhal cases, showed a pathology which could by any stretch of the imagination be designated as catarrhal, unless that term here means something very different than it does in any other part of the body; second, that all of these grave pathological changes in the appendix had taken place without causing general disturbance enough to put the patient in bed for a single day. All but one of them contained conditions which I should have considered as incompatible with the clinical histories. A search of the literature, however, showed me that these observations were not without ample support and convinced me that the term catarrhal appendicitis is not only meaningless but so gravely misleading that our ideas of chronic appendicitis must undergo some rather far-reaching modifications. To this end I wish to gather together here various clinical and pathological observations which stand in the literature.

First, it has been frequently pointed out and is the experience of all who do a considerable amount of appendiceal work, as who does not, that neither the clinical histories nor the clinical conditions are any guide to the extent of the pathological phenomena which may be present within the abdomen. Many observers have commented on the singular lack of correspondence between the findings and the clinical histories, both as to the surprising lack of pathological changes in cases with severe clinical manifestations, and in regard to the ofttimes astonishingly extensive changes involving unexpectedly severe and dangerous operations after the mildest of clinical histories. Moschcowitz and Moschcowitz (cited above) say "Acute catarrhal appendicitis. The course is usually milder than the destructive variety. The onset is not so stormy, there is usually no chill, etc., etc.—*As we know from experience, however, that these symptoms are deceptive and that cases like those above described can hide a gangrenous or even a perforated appendix, we have found it advisable to operate on many of these at once.*" The italics are mine. W. Hagen, in the *Beiträge zur klinische Chirurgie*, Vol. XLVI, p. 177, reports several severe interval cases without marked physical findings. Such references could be multiplied indefinitely. Moreover, there is a very considerable number of cases in the literature in which severe inflammations of the appendix have been demonstrated that have caused no symptoms that could in any way be reasonably ascribed to the appendix, prior to the operation or post-mortem. Of these I would here refer to those which have been reported by von Haberer at the Naturforscherversammlung in Dresden, referred to by Goedecke, which embrace a series of seven cases of advanced age who were afflicted with the severest obstipation, with great emaciation, in whom there were no abnormal findings over the abdomen, no tenderness over McBurney's point, nor any previous history of appendicitis, nor any point or jot upon which to hang a diagnosis of appendicitis. And yet at the performance of an exploratory laparotomy there was found in each extensive adhesions on and about the appendix with thickening and kinking of this organ, and scars in the mesenteriolum. No malignant growth of any nature was present anywhere in the abdominal cavity. All recovered after removal of the pathology about the appendix. Haberer considered these symptomless cases of appendicitis to be peculiar to advanced age, but Goedecke, in a communication from the clinic of Sonnenberg of Berlin (*Deutsche Zeitschrift, für Chirurgie*, Vol. 95, p. 320), reports six cases in young individuals, all of whom were operated on for acute ileus, in whom the cause of the ileus was found to be adhesions and scar contractions of the appendix and mesenteriolum, due to past and present inflammations of the appendix. He declares that not one of these patients had either in his history nor in his clinical findings a single symptom which ought to have led to a suspicion of an appendiceal process. Ewald, Sonnen-

berg, and Sprengel have described a type of appendicitis which they have variously designated an appendicitis larvata, or latent appendicitis, in which the diagnosis is very difficult because symptoms referable to other organs occupy the foreground of the picture. These symptoms may direct suspicion to the stomach, liver, gall-bladder, bladder, or female adnexa, or may show such general nervousness and debility as to appear under the picture of a neurasthenia or a hysteria. They even mention cases in which disturbance of the heart function was the dominating feature of the clinical picture. On the other hand, although not so often commented upon in the literature, the symptoms may be unusually severe and the alterations in the appendix found at the operating table surprisingly slight. I think all of us have at times felt a sense of disappointment upon finding in a case with severe symptoms, an appendix little, if any, altered in its gross appearance, only to observe a very satisfactory restoration to health after the removal of the inoffensive appearing organ. A most striking case of this kind came within my own experience a short time ago. A young married woman, the mother of one child, had been the victim of two very severe attacks of what appeared to be acute appendicitis. After the second attack she did not recover her general good health, but remained in a condition of prostration. Although her temperature did not run above 99°, she complained of recurrent colicky pains over the entire abdomen, with a constant tenderness and soreness over the right side. The pains extended into the right limb to such a degree that she was unable to walk or straighten the affected leg and she was practically confined to her bed. This condition had continued for a couple of months and was slowly growing worse. There was a definite area of greatest tenderness over McBurney's point. At the operation we found at the site of the appendix a tiny tag of mesenteriolum, and upon it a tiny appendix of the diameter of the lead of a lead pencil and about one-quarter of an inch long, the nature of which could not be certainly determined until it was under the microscope. It was adherent to nothing and showed no signs of present inflammation. A thorough exploration of the abdominal cavity failed to show any other diseased condition and the abdomen was reluctantly closed with a distinct sense of failure. To our surprise her recovery was as rapid as it was complete.

Wherein lies the explanation of this complete lack of correspondence between the symptoms and the pathological findings which so often obtains in appendiceal cases? The observations of Lennander upon the sensibility of the various portions of the abdominal cavity, which have been painstakingly established and amply corroborated, furnish a full and complete explanation of the variations which have been described. Lennander, in his articles on the sensibility of the abdominal structures (*Centralblatt f. Chirurgie*, 1901, S. 2, *Mitteilungen a. d. Grenzgebiete d. Med. u. Chirurgie*, Bd. X, 1903, S. 3, 1906, Bd. XV, und XVI, *Deutsche Zeitschrift für Chirurgie*, Bd. 73-4) shows from observations made at the operating table under local anesthesia, of which he makes the most extensive use, that all the organs which are supplied only by the sympathetic and the vagus below the origin of the recurrent, have no sensation for pain, pressure, heat, or cold. All pain in the abdomen arises from irritation of the nerves in the parietal peritoneum, derived from the intercostal, lumbar, sacral, and phrenic nerves. His work has been sustained by Bier, Propping, Hain, and others, and I may say that in three laparotomies performed under local anesthesia I have taken occasion to corroborate to my own satisfaction the main points of Lennander's observations.

In this paper we must of necessity ignore all of the far-reaching conclusions of import to surgery which arise out of Lennander's observations, and neither can we enter into the interesting contention which has arisen as a corollary concerning the origin of the pain of intestinal colic, but must confine ourselves to those considerations which have a direct bearing upon the interpretation of the processes which have their seat in the appendix. Lennander has shown that the entire intestine, including the appendix, is without sensation. It may be handled, pinched, cut, or torn, without exciting sensation of pain. Only when the trauma is so applied as to make traction upon the mesentery and bring into play the branches of the spinal nerves which run in the posterior parietal peritoneum, is pain produced. So in inflammatory conditions we may conclude that as long as the inflammatory process is confined to the appendix alone we have no pain produced and only when it extends by contiguity to the anterior or lateral peritoneum, or more commonly by continuity along the lymphatics of the mesenteriolum to the posterior parietal peritoneum is pain appreciated by the patient. Lennander has already pointed out that McBurney's point, the seat of tenderness in chronic appendicitis and the diagnostic point of tenderness in all forms, corresponds not to the location of the appendix but to the location of that point where the lymphatics of the mesenteriolum first meet the sensory branches of the spinal nerves at the root of the mesenteriolum. (*Mitteilungen a. d. Grenzgebiete der Medizin und Chir.*, Vol. XV, p. 475.)

With these considerations in view one can now easily explain to himself all the many variations which occur in the appendiceal picture. It is now plain how even perforations of the appendix might occur in processes sharply limited to the appendix proper without the production of great pain or disability. On the other hand, one can understand that if the greater part of the chronic process which had its origin in the appendix, were played out in the derived lymphatics in direct contiguity with the posterior peritoneal subserous sensory nerve fibers, the sensory disturbance might well be entirely out of proportion to the gross findings present in the appendix. These considerations will also explain the perplexing findings with which we have all met in cases who have been subject to a sudden severe attack without any evidence of a previous appendiceal inflammation, and yet in whom the appendiceal region shows dense adhesions and inflammatory conditions which we cannot conceive of as having been produced within the few hours or days of the acute attack which preceded the operation.

Knowing as we do that the entire intestinal tract is subject to catarrhal conditions, *i.e.* to mild inflammatory conditions involving only the parenchymatous layer and accompanied by a hypersecretion of mucus, it would be absurd to contend that the appendix, in every way part and parcel of that intestine and identical in structure and function,

alone was immune from such a condition. On the other hand, it is equally absurd on sober second thought to assume that so small an area of intestinal surface as the appendix constitutes could produce such surprising symptoms as to stand out from the rest of the picture of intestinal catarrh unless we should assume that the mucus were in some way obstructed from free outflow from the appendiceal canal. That this does occur in high grades of occlusion the occurrence of mucocele is evidence, but if it occurs in lesser grades of stenosis sufficiently to produce appendiceal colic it is strange that we do not more often meet with appendices distended with mucus at the operating table. In fact, in view of the predominance of lymphoid elements in the appendix and the types of inflammation usually found upon microscopical examination of appendices, it is my opinion that the primary inflammation of the appendix is rather lymphoid than catarrhal in nature. In fact Aschoff, in an article not accessible to me, is said to have demonstrated that the primary seat of inflammation in the appendix is the lymph follicle.

In view of all the assembled facts it is easiest to believe that although the appendix in common with the rest of the intestinal canal may be subject to catarrhal inflammations the symptoms arising from it are not sufficient to make themselves evident from a clinical viewpoint unless there is a complete stenosis of the appendiceal canal, and that the low grades of appendicitis that we see clinically are not due to a catarrhal inflammation at all, but to ordinary inflammatory processes caused by the pus organisms, differing in no way from inflammatory processes as known elsewhere in the body, either in their nature or in their capacity for exacerbation and destructive action. In view of what has been said the inquiry naturally arises as to how frequently inflammatory conditions of the appendix exist which have caused few or no symptoms. There is evidence available that it is very frequent. Kümmel, in the *Archiv für klinisch Chir.*, Bd. 92, p. 371, quotes Aschoff, the great German pathologist, as stating upon the basis of his enormous post-mortem work that four-fifths of all adult mankind show disease of the appendix at post-mortem. Siegfried Oberdorfer (*Mitteilungen a. d. Grenzgebiete*, Vol. XV, p. 653), in a report based upon 600 autopsies in which he subjected the appendices to exact and largely microscopical examination, says that in the large majority of cases he found that the appendix had passed through a previous inflammation, "so that," he says, "completely normal appendices belong among the greatest rarities." Ribbert, who was the father of the now exploded idea of physiological obliteration of the appendix, said that "inflammation of the appendix must be extraordinarily more frequent than supposed, because obliteration occurred so frequently." Oberndorfer, commenting on the above remark, says: "We come to the conclusion, from our observation, that this extraordinarily frequent occurrence is actually a fact and that not only obliterative appendices, but nearly all appendices show alterations which are to be referred to inflammatory processes." Much more authority will be readily found upon search among the special writings of those who have devoted themselves to the study of pathology only, which will substantiate this idea, which, indeed, has been well recognized among the pathologists proper for a long time, and, indeed, has been the nub about which have been waged some very pretty controversies, upon one of which we will shortly touch. But I think the weight of authority of the names and work above quoted suffice to enable even those to whom the idea is new to accept it as a fact that the appendices of at least the large majority of adult humanity are at some time during life the seat of inflammatory changes. That these inflammations did not in the majority of cases produce symptoms which were recognizable of course goes without saying.

However, all of the men above mentioned, with the single exception of Aschoff, felt themselves obliged to assume that the inflammatory changes discovered at post-mortem were caused by a chronic inflammation, in order to account for the lack of symptoms which accompanied it, an acute inflammation in the abdominal cavity, of the grade necessary to explain the findings which they observed, that did not produce pain and other recognizable symptoms, being to their minds unthinkable, in the light of the knowledge which they then possessed. To explain this anomalous situation they assumed a form of chronic inflammation not known elsewhere in the bowel and which, moreover, had and has never been observed in the actual process of transpiration. No such subterfuge was possible to the masterly mind of Aschoff, and, though he had at that time no explanation to offer of the difficulties mentioned, he baldly states that the inflammatory changes observed in these cases must have been caused by acute processes. In the light of Lennander's studies upon the sensitiveness of the various abdominal structures, it is easy for us to clear away the difficulties which confused these older writers and account for the symptomless course of these processes without assuming a hypothetical form of chronic inflammation.

The question of the frequency of such perforations as I have described arises. There are a large number of healed perforations reported in the literature, although usually the history of the cases does not accompany the report. Most of these have been reported under the heading of diverticula or false diverticula of the appendix. While this misleading title has been adhered to by pathologists as well as clinicians, many of the former have recognized the true nature of these abnormalities. Indeed, there are in the literature a number of cases which are direct parallels to the cases which I have reported in this paper, in which the perforations were found in cases which did not present corresponding histories. Max von Brunn, in *Beiträge zur klinische Chir.*, Vol. XLVI, p. 67, reports a number of cases of diverticula of the appendix and publishes a number of most beautiful and instructive plates of the microscopical pictures found. He says: "If we now turn to the question of the origin of the diverticula, it is easy to demonstrate that they arise upon an inflammatory basis and have apparently all been preceded by a perforative appendicitis." He quotes a number of cases from various authors, among them several from Mundt. One of these is a diverticulum which was due to perforation in a man who died of acute heart trouble, and who had never had an attack of appendicitis. Mundt explains this "most peculiar case, which," he says, "stands isolated in the literature," upon the basis of a chronic inflammation. Von Brunn also cites three cases from Lejars and Menetier, who found such diverticula with slight clinical histories. Upcott, in *Sur-*

gery, Gynecology, and Obstetrics, Vol. VI, p. 454, reports a similar case. And George Ben Johnson, in the same volume, on page 614, reports a perforation in a case where the patient's history was "absolutely negative as to previous attacks of abdominal pain." Thus we may conclude that inflammation of the appendix is so very common that four-fifths of all mankind show that they have passed through it before death overtakes them, and we may conclude that these inflammatory processes, whether they produce symptoms or not, are of the same nature and sort, differing only in degree, as the more severe inflammations with which we are accustomed to associate thoughts of danger and death. Shall we wonder, then, that as our knowledge of appendicitis grows the number of cases which seem to demand operation grows? Certainly the ravages of appendicitis in the face of the progress of surgery are still frightful. Kümmel, in an address before the German Surgical Association in 1910 (reported in *Archiv für klinische Chir.*, Bd. 92, p. 371), states that upon the basis of Prussian statistics the greatest mortality from appendicitis occurs between the ages of ten and twenty-five, and that at this age more people die of appendicitis than of all other diseases put together. I regret that no reliable American statistics are available upon this point. Undoubtedly our mortality is a little lower than that of Prussia, for the American profession is a little less conservative than the German profession—a little quicker to operate. Yet one has only to look about him, only to search his individual memory, to realize that the death rate from this disease is still enormous even in this country. A diminution of this mortality seems to be possible only through, first, the abandonment of the idea that there are any innocuous forms of appendicitis, especially the abandonment of the term and the idea of catarrhal appendicitis, the recognition that all recognizable forms of appendicitis, no matter how slight the phenomenon, bear great possibilities of danger, and secondly, through a strenuous effort to so increase our diagnostic resources in this disease that we will eventually be able to recognize those latent forms which at present escape our diagnostic acumen until the patient has already been overtaken by a condition of grave immediate danger.

The following conclusions seem warranted from the above researches and argument. First, the gross appearance of the appendix is never a sufficient criterion of the severity of the pathology present. Second, absolutely no idea of the nature or severity of the inflammation of the appendix can be formed from the clinical symptoms. Third, appendicitis may run its course through perforation of the appendix and subsequent healing without symptoms which will admit of its recognition, nor, indeed, of severe symptoms of any kind. Fourth, the clinical condition designated as catarrhal appendicitis does not have a catarrhal inflammation of the appendiceal mucosa as a pathological basis and is, therefore, a misnomer which is dangerously misleading to the general profession. Fifth, no catarrhal inflammation truly speaking has ever been described as a pathological finding in appendicitis. The term should for all these reasons be definitely abandoned. Lastly, appendicitis is much more frequent than usually assumed or than is indicated by our present means of diagnosis. The mortality of this disease is still of grave proportions and the only measure which offers any prospect of immediate reduction of this mortality is early operation upon all recognizable cases.

Case I.—Miss M. R.—Appendix, 12 cm. long. Diameter at tip, .7 cm.; middle, .8 cm; cecal end, .5 cm. Total number of sections, 690. Block I.—Tip. Some sections were made from extreme tip so as to include just so much mucosa as to simulate an obliteration of the lumen. These sections are distinctly characterized by the presence of longitudinal bundles intruding upon and even within the circle of the circular bundles. The bundles of the two layers seem to run more or less together, to anastomose. Normal lumen containing detritus. Epithelium perfect. Glands rather few. Follicles increased in number, 9 in section saved. Intrusion of connective tissue upon mucosa. Round cell infiltration of submucosa. Muscularis normal. Number of sections from this block 82. Saved, 5. Block II.—Near tip. Lumen large, containing polymorphonuclear cells. Glandular layer atrophic. Lymph follicles increased, 8 to 10. Submucosa normal. Muscularis normal, except pierced by good sized blood vessel almost opposite mesenteriolum. Peritoneal coat dilated capillaries or adhesions with peritoneal cysts (which?). Number of sections from this block, 185. Saved, 2 sections. Block III.—Middle. Lumen normal or a little large. Epithelium low. Glands few. Lymphoid tissue much increased. Submucosa sparse, and round cell infiltration. Muscular coat normal. Peritoneal coat dilated capillaries containing polymorphonuclears. Number of sections from this block, 87. Saved, 1. Block IV.—Near cecal end. Lumen small, .2 cm. in diameter, containing fecal matter. Epithelium low but complete. Glands few and short. Lymphoid tissue shows great hypertrophy, 10 to 12 nodes. Very large and much lymphoid tissue between. Muscular coat normal. Some sections show fresh hemorrhage into lymphoid tissue. One section shows a blood vessel piercing muscular coat away from the mesenteriolum. Number of sections from this block, 91. One section saved. Block V.—Cecal end. Lumen completely blocked by an egg or seed (round cells) with small spines all about the capsule. Polymorphonuclears within the capsule and a few outside in the lumen of the appendix. Epithelium very low. No marked reaction of the presence of the foreign body. Moderate number of polymorphonuclears under the epithelium. Glands decreased in number. Lymphoid tissue decreased in amount. Submucosa increased. Muscularis normal. Number of sections from this block, 67.

Case II.—Miss G. G.—Appendix, 7 cm. long. Diameter at tip, .5 cm.; diameter 5mm. from tip, .8 cm.; middle, .5 cm.; cecal end, .7 cm. Injected surface and appearance of

Fig. 1—Perforation. Case II.

concretion at .5 cm. from tip. Block I.—Tip. Shows obliteration of lumen by connective tissue. No epithelium seen, few remnants of lymphoid tissue. Fat invading obliterating connective tissue to some extent. No sections saved. Number of sections examined from this block, 47. Block II.—Proximal from block I. Lumen wide, contains

concretion. Glandular layer rich. Follicles many, 8 or 9. Moderate distortion of mucous tube. Submucosa rich and fat. Muscular layer normal, and peritoneal coat normal. Small fresh hemorrhages throughout tissues. Number of sections examined, 140. None saved. Block III.—Proximal from block II. Two types of section. One type has a lumen of 2 by 3 mm. in diameter. Epithelium low but perfect. Little fecal matter in lumen. Glands many, but short. Lymph nodes many, 10 to 12. Mucous tube evidently distorted, as there are glands cut longitudinally and transversely, and the lumen is usually eccentric. Type 2. Lumen large, 5 mm. in diameter, filled with fecal matter containing vegetable fibres and a seed. Epithelium low, missing in spots, but no inflammatory reaction. Lymph nodes, 5 or 6, small. Submucosa, and muscularis, and peritoneum normal. Number of sections examined from this block, 81. No sections saved. Block IV.—Proximal from III, and middle of appendix. Lumen wide, contains fecal concretion. Mucous tube distorted, drawn close to muscular layer on one side, and at a considerable distance from it on the other side, interval being occupied by connective tissue and fat. The epithelial layer shows glands in transverse and longitudinal sections. Lymph follicles are large and plentiful on side, on which there is a considerable interval between mucosa and muscularis. They are small and scant on the other side. Number of sections examined from this block, 46. No sections saved. Blocks V. and VI.—Proximal from IV. Lumen wide, Y shaped. Considerable distortion of the mucous tube. Little hemorrhage. Number of sections, 56. None saved. Block VII. —Cecal end. Some sections are incomplete on one side, the lumen standing open so as to make a horseshoe. The opening of the horseshoe and the lumen are blocked with a large fragment of mucosa. There is hemorrhage about the fragments, and there are round and polymorphonuclear cells in the hemorrhage. Some sections show a direct continuity between the legs of the horseshoe and the large fragment blocking the opening. There is a fine fibrinous clot covering all exposed surfaces. There is hemorrhage into the mucosa at various points about the lumen, containing polymorphonuclears. Fresh perforation. Number of sections examined of this block, 142. Three sections saved. (See Figure 1.)

Case III.—Miss R. M.—Appendix about 11 cm. long. Irregular in diameter, contains concretion near tip. Tip, .5 cm.; middle, .5 cm.; cecal end, .6 cm. Total number of sections, 208. Block I.—Tip. Concretion in lumen. Lumen large, epithelium low, glands few, and atrophic. Follicles, only traces. Epithelium shows areas of ulceration. Muscular layer thin but complete. Number of sections of

Fig. 2—Extreme distortion of the mucous tube, showing two lumens. Case III.

this block, 25. Saved, 2. Block II.—Near tip. Large lumen, empty (concretion lost). Glandular layer thin, but many glands short. Few nodes. Connective tissue layer thick, much fat. Muscularis thin but perfect. Sixty-four sections. None saved. Block III.—Middle. Large, perfect lumen, collapsed in middle of section. Lumen contains many pus cells. Epithelium perfect, except two areas of ulceration. Glands well developed. Ten to 11 follicles present. Mucous tube much distorted. *A second lumen* lined with epithelium and lined with glands, is present just under the muscularis, opposite to the mesenteric attachment, extending in a crescent one-half to three-fourths

Fig. 3—A peculiar healed perforation with prolapse of considerable mucous membrane. Case V.

of the circumference of the appendix. Muscularis thin but perfect. Three sections saved. Total number sections in this block, 51. Block IV.—Cecal end. Obliteration of lumen. In some sections remnants of mucosa, few glands, and a follicle. In others, no trace of mucosa but its place taken by a young connective tissue, in solid mass, whose lymphatics are filled with polymorphonuclear cells. Submucous connective tissue layer increased, filled with fat, and containing large blood vessels which contain polymorphonuclears. Muscular coat complete, but at mesenteric border a peculiar small pseudo-diverticulum. Adhesion on periphery. Number of sections examined of this block, 32. Three sections saved. (See Figure 2.)

Case IV.—Miss M. M.—Appendix, 12 cm. long, .7 cm. at tip, .8 cm. at middle, .5 at cecal end. Total number of sections made, 690. Block I.—Tip. Some sections made from extreme tip, where just so much of the mucosa was included as to simulate an obliteration of the lumen. These sections are distinctly characterized by the presence of longitudinal bundles intruding upon and even within the circle of the circular bundles. The bundles of the two layers seem to run more or less together, to anastomose. Normal lumen containing detritus. Epithelium perfect. Glands rather few. Follicles increased in number, 9 in section saved. Intrusion of C. T. upon mucosa, i. e., distortion of mucous tube. Round cell infiltration of submucosa. Muscularis normal. Number of sections of this block, 82. Five sections saved. Block II.—Near tip lumen, large, containing polymorphonuclears. Glandular layer atrophic. Lymph follicles increased, 8 to 10. Submucosa normal. Muscularis normal, except pierced by good sized blood vessel almost opposite mesenteriolum. Peritoneal coat shows dilated capillaries, or adhesions with cavities somewhat like peritoneal cysts (which?). Block III.—Near tip. Lumen small, 2 mm. in diameter, containing fecal matter. Epithelium low but complete. Glands few and short. Lymphoid tissue shows great hypertrophy, 10 to 12 nodes, very large and much lymphoid tissue between. Muscular coat normal. Some sections show fresh hemorrhage into lymphoid tissue. One section shows a blood vessel piercing muscular coat away from mesentery. This one section saved. Block IV.—Middle. Lumen normal, or a little large. Epithelium low. Glands few. Lymphoid tissue much increased. Submucosa sparse and round cell infiltration. Muscular coat normal. Peritoneal coat dilated capillaries containing polymorphonuclears. Number of sections of this block, 87. Saved, 1 section. Block V.—Near cecal end. Lumen irregular, 2 mm. in diameter. Epithelium intact. Glands rich. Follicles 8 to 9. Submucosa muscularis peritoneum normal. No sections saved.

Number of sections this block, 91. Block VI.—Cecal end. Lumen completely occluded by an egg or seed (round cells) with small spines all about the capsule. Polymorphonuclears within the capsule and a few in the lumen of the appendix. Epithelium very low. No marked reaction against the presence of foreign body. Moderate number of

Fig. 4—Distortion of the appendix due to the formation of an abscess between the mucous and muscular coats. Case VI.

polymorphonuclears under epithelium. Glands decreased in number. Lymphoid tissue decreased in amount. Submucosa increased, muscularis normal.

Case V.—Miss E. M.—Appendix about 7½ cm. long. Irregular in diameter. Contains three large concretions. Tip blunt hook shaped. Total number of sections, 184. Block I.—Tip. Cross section through protrusion of blunt hook shows it to be caused by an old healed perforation of the appendix, through which a portion of the mucosa has prolapsed and then the perforation has closed again. (See Microphotograph). Number of sections from this block, 83. Block II.—Middle. Very large lumen, irregular shape, columnar, epithelium low, and in places missing, glandular epithelium present in large quantities, most of glands cut transversely as rings, therefore section is not exactly trans-

Fig. 5—Pseudo-diverticulum. A condition simulating a healed perforation. Case VII.

verse of mucous tube. Seven to 8 follicles to section. Muscular layers thick, both circular and longitudinal layers are hypertrophied. Number of sections to this block, 34. Block III.—Cecal end. Complete obliteration. Some sections from this block show a lumen of varying sizes, others show obliteration with a little lymphoid tissue marking the former site of the lumen, others show obliteration in which a connective tissue string has replaced the mucous tube, leaving not a trace of parenchymatous tissue. Number of sections examined from this block, 67. Saved, (See Figure 3.)

Case VI.—M. B.—Appendix about 7 cm. long. Tip, .4

Fig. 6—Old healed perforation with obliteration. Case VIII.

cm. in diameter; middle, .5 cm.; cecal end, .5 cm. Total number of sections, 174. Block I.—Obliteration. Tip. Number of sections examined, 73. One section saved. Block II.—Middle. Lumen, .2 cm. Contains fecal matter and pus. Glands normal. Follicles, 6. Muscular coat normal. Number of sections from this block, 35. None saved. Block III.—Cecal end. Muscular coat not thickened Lymphatic follicles, 6 and 7. Lumen almost entirely occupied by double fold of mucosa which projects into lumen from a broad base on one side. From the same point the muscularis is folded outward into a tit-like projection from the appendix wall, so that the fold of mucosa and the fold of muscularis lie base to base. Evidently a small abscess has formed in the appendix wall, which has raised the mucosa away from the muscularis and stretched out both layers. When the abscess broke through the mucosa, as shown in one section, the cavity so collapsed as to project the fold of mucosa into the lumen and a fold of muscularis in an opposite direction. Pus cells are present in the lumen beyond the mucous fold and in the fold itself, and in the blood vessels at the base of the fold, also a collection in the base of the fold in one section. Number of sections from this block, 66. Nine sections saved. (See Figure 4.)

Case VII.—Mrs. J. S.—Appendix 12 cm. long, .7 cm. in diameter at tip, .8 at middle, .5 at cecal end. Total number of sections, 321. Block I.—Tip. Lumen, wide, contains inspissated fecal matter. Epithelium in places low and free from glands. In places epithelium absent, and infiltration of polymorphonuclears. Polymorphonuclears in masses in places between concretion and epithelium in lumen of the appendix. Number of sections from this block, 79. One section saved. Shows a blood vessel piercing the muscularis, *not* at the mesenteriolum. Block II.—Middle. Lumen small, contains masses of polymorphonuclear cells. Epithelium fairly intact. Some polymorphonuclears under epithelium in lymphoid tissue. Lymphoid tissue rich. Five to 7 follicles. On mesenteric border break in muscularis, and lymph follicle protruding through the break. Lymph follicle distorted into a goblet shape, with the small point in the break. Diverticulum is along a blood vessel with thickened walls. Normal. Number of sections from this block, 119. Saved, 9 sections. Block III.—Cecal end. Through poor preparation the muscularis is lost in specimens saved. Intact epithelial layer. Lymphoid layer rich. Lumen contains polyp composed of lymphoid tissue surrounded by normal epithelial layer, thrown into many convolutions which are variously cut across. It is a portion of the mucosa protruding into the lumen as a polyp. Two sections saved. One shows base of polyp, the other shows

tip hanging free in lumen of appendix. In places there are breaks in the epithelial covering of the polyp, and a slight polymorphonuclear infiltration. Number of sections from this block, 64. Two sections saved. (See Figure 5.)

Case VIII.—Mrs. I. L.—Appendix about 5½ cm. long. Diameter at tip, .5 cm.; middle, .6, and cecal end, .5. Total number of sections examined, 176. Block I.—Tip. Obliteration of lumen a short distance below tip, with extreme distortion of relations. Some sections show a protruding loop of muscularis opposite the mesenteric border, with only a thin string of circular fibres completing the circle within. The lumen is obliterated at this level and such remnants of mucosa as are present are drawn close up against this weakened spot in the muscularis. Diagnosis, healed perforation. Total number of sections from this block, 102. Saved 8 sections. Block II.—Middle. Lumen large, epithelium low, incomplete in places, with continuous strings of polymorphonuclears beginning in lymph follicles and extending into lumen. Glands much decreased in number. In section saved a lymph follicle seemingly emptying into lumen. Fat of submucosa increased in amount. Muscular layers normal. Sections from this block, 45. One section saved. Block III.—Cecal end. Lumen large. Thin walled mucous tube composed mostly of glandular elements. Lymphoid tissue decreased. Submucosa increased. Muscularis much distorted. Number of sections from this block, 29. None saved. (See Figure 6.)

BACTERIOLOGICAL STUDY OF A CASE OF HEMORRHAGIC MYELOMALACIA.*

By GUSTAVE ADOLPH RUECK, M.D.,

NEW YORK.

The organism here described has been studied and reported upon on account of certain points in its biology, which seem to separate it from the *Micrococcus intracellularis* of Weichselbaum and because of the peculiar destructive lesion with which it was found associated in the spinal cord of man. The history of the patient was as follows:

H. S., Hungarian, 50 years of age, married, tailor, in St. Francis Hospital from October 27 to November 4, 1910, in the service of Dr. John Rogers. *Family history:* Parents dead. No tuberculosis or cancer in the family. *Previous history:* He had some of the diseases common to childhood, and had gonorrhea when a youth. Two years ago he noticed a change in his voice, and this condition became permanent. He used alcohol very moderately. His wife had three abortions and gave birth to one living child. She suffered from a slight cough off and on but was well otherwise. *Status:* Three weeks before admission he came from work complaining of general malaise, abdominal pain, and aneuresis. The bowels had not moved for several days. He entered St. Francis Hospital on the advice of his physician. While on the way to the hospital in an elevated train he was suddenly taken with weakness in the legs and prostration. He was transferred to an ambulance and brought to St. Francis Hospital where he was admitted to the surgical division. *Chief complaint on admission:* Retention of urine, pain in the abdomen, especially in the hypogastric region, and asthenia.

Physical examination, October 28, 1910.—Height, 5 feet, 6 inches; weight, about 135 pounds; poorly nourished; the eyes react sluggishly to light. There is no clinical report of the examination of lungs and heart. Urine, October 28, 1910, dark amber, cloudy, acid, trace of albumin, no sugar. Many red blood cells, few hyaline and granular casts, few white cells, some débris. There is a band of hyperesthesia over the abdomen, a fecal impaction of four days standing and retention of urine. The right leg is paralyzed. There is bilateral loss of knee-jerks. Sensation is retained in both legs.

October 29, 1910. The left leg is now paralyzed. There is a loss of sensation to pain and temperature in both legs. The line of hyperesthesia on the abdomen is extending further up.

October 30, 1910. Same as above.

November 1 and 2, 1910. Patient is very weak and eats little. There is a loss of sensation up to his breast and hyperesthesia above a line drawn through both nipples.

November, 4, 1910. Exitus.

*From the Department of Bacteriology, College of Physicians and Surgeons, Columbia University. (The publication of this paper has been delayed by the illness and death of Dr. P. H. Hiss.)

Clinical diagnoses: Acute Landry's paralysis. (Dr. John Rogers.) Acute infectious disease of unknown bacteriological origin of the spinal cord. (Dr. J. J. MacPhee.)

Autopsy by Dr. John H. Larkin, November 4, 1910. Anatomical diagnosis: (1) Chronic pulmonary tuberculosis. (2) Lobar pneumonia. (3) Fibrinopurulent meningitis and hemorrhagic myelomalacia. (Large segments of the spinal cord being entirely liquefied.)

Bacteriological Examination.—Although the autopsy revealed chronic pulmonary tuberculosis and lobar pneumonia, a bacteriological examination of the lung was not made and it was therefore not determined whether the organism described below was present in the lung and the possible cause of the pneumonia.

Cultures of the spinal cord were taken under sterile conditions. About 3 c.c. of the slightly turbid cerebrospinal fluid was aspirated and transferred to agar slants and into meat infusion bouillon in test tubes. The next day the fluid on agar slant was centrifugalized. In the smears made from the sediment a micrococcus was found similar in its morphology to the micrococcus of epidemic cerebrospinal meningitis. The culture appeared to be made up largely of one type of organism. Only a few rods were present. They had the same diameter as the micrococcus and disappeared entirely after several transplantations. This disappearance was at first thought to be due to the more vigorous growth of the coccus, but later it was found that the rods were "bacillary forms" of the coccus.

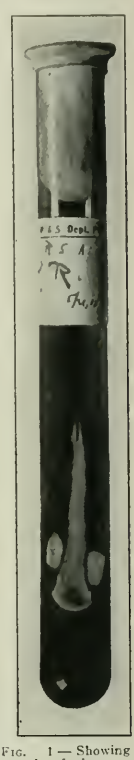

Fig. 1.—Showing growth of the new organism on slanted rabbit-serum agar.

Morphology.—Smears of the exudate and cultures were made. The organism was found to be a micrococcus of the size of *Micrococcus intracellularis* of Weichselbaum. It appeared as a diplococcus, single, as tetrads, and in short chains of four. The ratio of length to breadth was 1:1. The juxtaposed surface of the diplococcus was flat. It appeared extra- and intracellularly. In smears from the twenty-four-hour cultures a few "bacillary forms" were present and in the beginning a contamination was suspected, but these bacillary forms disappeared from time to time after careful plating and the organism was known to be in pure culture.* A year after the isolation of the organism this part of the morphology was taken up again. The "bacillary forms" and even a few long filaments appeared in smears made from twenty-four-hour cultures. After forty-eight hours, when the cocci had degenerated and stained faintly, the bacillary forms and filaments were found to be single cocci arranged in chains and held in position possibly by a common membrane. In all other respects the organism resembled the micrococcus of Weichselbaum. It had no capsule, no spores, and was also negative to Gram's method of staining. The surface colonies on blood-agar plates, when seen with the lower power, were finely granular and

*Verderame, in 1910, and others since have described micrococci which develop bacillary forms.

some of these were radiating from the center like a rosette, the red background shining through the colonies.

Growth on Various Media.—To complete the cultural study of this organism its growth on the various media was compared with that of strains of the allied species of meningococcus. A strain Fraymann (F.) of the micrococcus of epidemic cerebrospinal meningitis was obtained from Dr. Flexner of the Rockefeller Institute, and six meningococcus strains from Dr. Park of the Department of Health. Of these latter six organisms, Nos. 24 and 23 were fresh, 1, 20, 3, and 14 older cultures. The organism to be identified grew luxuriantly on all the media. The meningococcus of Weichselbaum was less vigorous and could be grown only with difficulty on ordinary meat-infusion-agar; on potatoes it did not grow at all. On neutral glucose (1 per cent.) meat-infusion-agar it seemed to thrive exceedingly well, forming a luxuriant mucous growth along the streak which resembled that of the meningococcus and of *B. mucosus capsulatus* of Friedlander. When touched with the platinum needle a long thread could be drawn out and when water was added the growth could be rolled up from the medium and moved in the water by the platinum needle just like a mass of mucus.

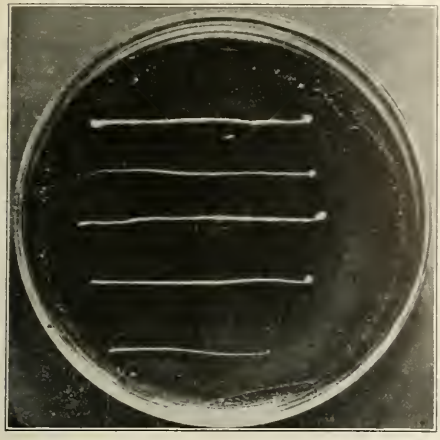

Fig. 2—Showing growth of *Micrococcus intracellularis* of Weichselbaum on plated agar

Meat-infusion-bouillon was turned slightly turbid within twenty-four hours by the unknown organism and meningococcus and there was no pellicle or sediment seen. After forty-eight hours the meningococcus had no pellicle, but a scanty grayish sediment. The broth containing the organism to be identified was, after forty-eight hours, very turbid, had a white pellicle and a grayish sediment. No change in the color of the medium was observed.

On Loeffler's coagulated serum-medium there was a luxuriant growth but no liquefaction of the medium. In glucose-meat-infusion broth in fermentation tubes there was no gas formation. The broth was turbid in the open and clear in the closed arm. After forty-eight hours a white pellicle appeared on the surface of the medium in the open arm and a grayish white sediment at the bend of the tube.

Stab cultures in gelatin tubes did not grow at room temperature.

In gelatin plates cultures developed without liquefaction of the medium.

Litmus milk was not coagulated, nor changed in its reaction, although a growth took place.

No indol was formed in Dunham's peptone broth.

Fermentation of Sugars.—In order to test the fermentation of this organism in different sugars lactose-litmus-agar and freshly prepared Hiss' serum water media were used. For comparison the seven strains of meningococcus mentioned above and one strain of *Micrococcus catarrhalis* were studied.

The unknown organism R. turned lactose-litmus agar very slightly acid at and near the streak six days after the inoculation. The different meningococcus strains and *Micrococcus catarrhalis* produced no change in this medium. The cultures in Hiss' media were kept at +37° C. Readings were made every twenty-four hours. In making the inoculation of the sugar series a heaped loopful of moist bacteria of an eighteen-hour growth on glucose agar was transferred to each tube. That the organisms were still alive in the sugar-media after seven days of incubation at 37° C. was proven by transfers to rabbit-serum-agar and glucose-meat-infusion-agar.

The experiment with Hiss' media brought out the following facts: The unknown organism R. fermented and coagulated dextrose and galactose completely in five days the first time it was tested and also five months later. Flexner's "strain Fraymann," after having been grown on artificial media for a long time, fermented dextrose and maltose much weaker in the last experiment than five months ago, the reaction becoming visible only after five days. In two tests levulose was fermented.

One organism (24) which was especially virulent and had been recently isolated, fermented dextrose, maltose, and levulose vigorously. Acid was formed in two days and coagulation was complete after four days. Three other forms of this species (23, 1, 20) fermented these three sugars weakly. Another (14) fermented and coagulated dextrose and maltose vigorously and levulose very faintly, whereas still another strain (3) had completely lost its power of fermentation of these sugars.

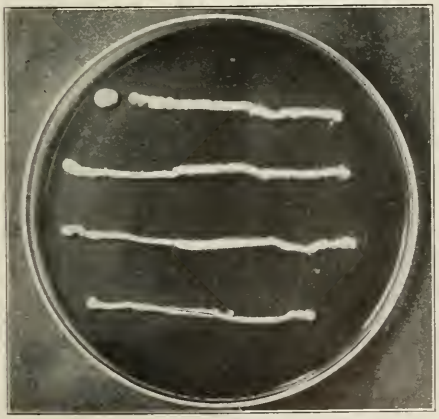

Fig. 3—Showing growth of the new organism on plated agar.

The *Micrococcus catarrhalis* tested did not ferment any of these sugars.

Thus seven cultures previously identified as typical meningococci fermented dextrose, maltose, and levulose, and one culture (3) none of the sugars tested.

The unknown micrococcus R. fermented dextrose and galactose and not maltose and levulose, and is, therefore, in this respect different from all these organisms, although it required, like them, several days to ferment its sugars.

Viability.—As the determination of viability has been found helpful in the differentiation of the *Meningococcus intracellularis* Weichselbaum from other organisms, the unknown organism R. and the seven meningococcus strains were grown at different temperatures. Micrococcus R. lived at room temperature, 20° to 21° C., in the thermostat at 37° C., and at 12° to 16° C. as long as the media were moist. The specimen kept in the ice box at 0° to 2° C. was alive after eighteen months. The other seven organisms were each transferred to four tubes of glucose-agar and, after having been in the thermostat at 37° C. for twenty-four hours they were placed in the ice box. In transferring, the loop of the platinum wire was drawn over the entire length of the surface of the culture medium so as not to miss any organisms still living, for organisms at the lower end, in the water of condensation, might have been killed by products of previous growth and, some at the upper end might have died on account of want of moisture. This is the result: One organism (23) lived in the ice box for five days. Two organisms (20 and 3) lived in the ice box for six days. Two organisms (1 and 14) lived in the ice box for seven days. One organism (F.) lived in the ice box for nine days. One organism (24) lived in the ice box for nearly six months.*

Then the eight organisms were each transferred to three tubes of glucose-agar and kept for 24 hours, one tube at room temperature, one at 40° to 41° C., and one at 12° to 16° C. The result was as follows: One organism (24) grew at all three temperatures. Four organisms (23, 20, 1 and 14) grew at room temperature and at 40° to 41° C. Two organisms (3 and F.) could thrive only at 40° to 41° C. Organism F. seemed to have lost its ability to grow at a temperature other than near to 37° C., for it behaved differently about four months previous to this experiment.†

The organisms R. and F. only were compared as to their viability in the dry state. For this purpose twenty-four hour cultures on glucose-agar were used. Several small smears were made on the bottom of each of several sterile petri-dishes which were kept in the dark at room temperature. Every day a drop of normal saline was added to a smear. A suspension of the dry bacteria was made and a loopful of this was transferred to slanted-glucose-agar tubes which were placed in the thermostat for twenty-four hours. Under these conditions organism R. lived eleven days, organism F. five days.

The Thermal Death Point.—Bettercourt and Franca, quoted by Kutscher, give the thermal death point of the micrococcus of epidemic cerebrospinal meningitis as follows: It is killed by moist heat at 60° C. in 1 minute.

Von Lingelsheim, quoted by Kutscher, states that the *meningococcus intracellularis* of Weichselbaum is killed by moist heat at 60° C. in 10 minutes.

Flexner states that suspensions of the diplococcus of epidemic cerebrospinal meningitis are killed when heated for 30 minutes to the temperature of 60° C.

The organism R. is killed by moist heat at a temperature of 60° C. in 75 minutes and at 64° C. in 10 minutes.

Agglutination.—In order to make the agglutination test three rabbits were immunized, one with "strain Fraymann" of epidemic cerebrospinal meningitis, the second with *Micrococcus catarrhalis*, and the third with the unknown organism R. A fourth serum was that from a rabbit immunized to a culture of the *Micrococcus mucosus capsulatus* obtained from Dr. Wadsworth. In testing the agglutinating power of the sera of these rabbits agglutination was noticed in the control of the normal rabbit serum and in normal saline also. This was due to the percentage of saline used, and a 0.5% saline solution was therefore substituted for the one containing 0.85% NaCl. Equal parts of the diluted sera and of the suspensions of the organisms to be tested were mixed in agglutination tubes and kept in the thermostat at 37° C. for two hours and then placed in the ice box for 18 hours.

The serum F. agglutinated its own organism in the dilution of 1:100, but did not act on organism R. or *Micrococcus mucosus capsulatus*.

The serum of organism R. agglutinated its own organism in the dilution of 1:4000 within one hour. It was therefore very active but it agglutinated organism F. only partially in dilutions up to 100 within 24 hours, forming a slight sediment and leaving the supernatant fluid turbid. *Micrococcus catarrhalis* was "salted out" and had to be excluded. The serum did not agglutinate a suspension of *Micrococcus mucosus capsulatus*.

The serum of the rabbit immunized with micrococcus catarrhalis agglutinated its own organism in dilutions up to 1 to 400 or was salted out by the ½ per cent. saline solution. No sediment was seen in the dilutions of 1:1000 and 1:4000. The liquid appeared clear after twenty-four hours, the organism having undergone autolysis. This serum did not act on organism R. F. or *Micrococcus mucosus capsulatus*.

Although it did not ferment any sugars the *Micrococcus catarrhalis* was tested because it was otherwise similar to organism R. in its morphological and cultural appearance.

Micrococcus mucosus capsulatus also failed to ferment the sugars, but its growth and morphology apart from capsule formation was strikingly similar to micrococcus R., especially in its ability to produce a mucous material on glucose-agar.

A polyvalent antimeningococcus horse-serum was obtained from Dr. Flexner and organism R. and the seven strains of the micrococcus of cerebrospinal meningitis were tested as to their agglutinative action. (A polyvalent serum prevents the in-

*Organism 24 from the Department of Health seems, according to this experiment, not to be a true meningococcus of Weichselbaum.

†December 7, 1910. F. was transferred to glucose-agar. At room temperature (21° C.) it showed after 24 hours a week but distinctly visible growth, like a yellowish white veil. The surface of the medium, kept at 16° C., was roughened along the streak and near the water of condensation. With transmitted light and a dark background the growth appeared of a slightly lighter color than the medium. There were three colonies slightly raised and easily visible near the water of condensation. The rest of the growth could only be noticed on careful examination, and was similar to that of a pneumococcus after having been cultivated for a long time on meat-infusion-agar. In the water bath, at 41.4° C. it grew well.

dividual characteristics of the different organisms from becoming prominent.)

This serum did not agglutinate organism R. at all. The others were agglutinated in dilutions of 1:40 and 1:100.

Organisms 14 and 24 formed a group by themselves, as they were even agglutinated by a ½% saline solution. According to these tests organism R. is not a strain of *Micrococcus intracellularis* of Weichselbaum.*

The pathogenicity of this organism was only tried on rabbits. Quantities of 2 c.c. of a 24-hour growth in bouillon injected intravenously killed rabbits weighing 1200 grams in 18 hours. The organism was recovered from the heart blood. Quantities less than 2 c.c. injected intravenously failed to kill, the animal invariably recovering. Attempts to exalt the virulence of this organism in rabbits were not successful. Intraspinous inoculations with 1/5 of a 24 hour agar culture suspended in 1 c.c. saline killed a rabbit of 1500 to 1800 grams within 18 hours. There was apparently no difference in the action of washed or unwashed organisms. In

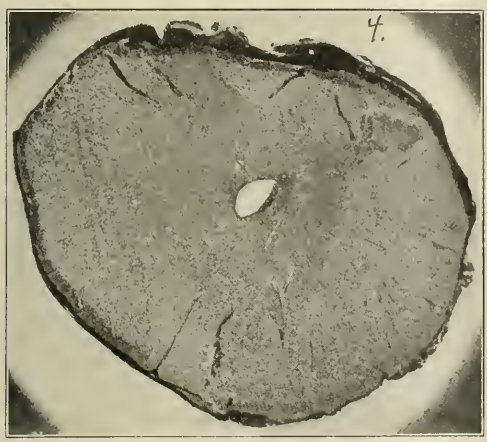

Fig. 4—Section of spinal cord in lumbar region of rabbit No. 7 (low power).

order to determine whether the effect of these inoculations was due to the development of the organisms as parasites or to the toxic action of the culture introduced I inoculated rabbits intravenously with 24-hour broth culture filtrates free from bacteria. Four c.c. of the filtrate would kill a rabbit weighing 1200 grams in 16 hours. The organism was not recovered from the heart blood in these cases.

These experiments prove that the cells of the micrococcus R. contain poison and also are in a degree parasitic.

Intraspinous Inoculation of Animals.—For purposes of control I inoculated one rabbit with the meningococcus (strain Fraymann). One-fifth of a 24-hour agar culture suspended in 1 c.c. salt solution was injected under the dura of the spinal cord by lumbar puncture. The following day the rabbit was sick, nervous, and excitable; the hind legs were paralyzed. These symptoms increased, the paralysis extending upward and the temperature falling below normal until the animal died the sixth day after inoculation. At autopsy a few of the organisms were found in the cord but they were numerous in the heart's blood. The cultures were pure. This rabbit gave symptoms and lesions of ascending paralysis seen in man. There were no lesions of cerebrospinal meningitis, simply a degeneration of nerve cells and their processes of brain and cord.

Then six normal rabbits weighing from 1500 to 1800 grams were each inoculated intraspinously with a suspension in 1 c.c. saline of the fifth part of washed micrococci R. of a 24-hour growth on agar. Immediately after the inoculation the animals showed no signs of illness and their appetite was good. Four to six hours later they began to appear sick, were lying on their belly, did not like to be disturbed, and had no appetite. No symptoms of paralysis were noticed. All these animals died within 18 hours.

At autopsy pure cultures of the organism were obtained from the cerebrospinal fluid, the substance of cord and brain, the heart blood, liver, spleen, pleural and peritoneal fluids and the urine but not from the bile. In one instance, rabbit No. 7, I was able to trace by means of cultures the passage of this organism from the cranial cavity, through the cribriform plate into the upper chamber of the nose. On microscopic examination a more or less pronounced fibrinopurulent meningitis and necrosis of brain and cord were noticed. The destruction was moderate in the substance of the brain and greatest in the lateral columns of the cord where areas of liquefaction could be seen. Sections of the cord of rabbit No. 12 showed round-cell infiltrations of the cord along the posterior horns. The central canal of the cord was not dilated. Free hemorrhage into the cord was not observed. The sections of the kidneys revealed acute parenchymatous nephritis followed by necrosis. The liver was necrotic and had areas of liquefaction and free hemorrhage. Spleen and bladder were congested. The lung was congested. In rabbits Nos. 11 and 12 lobar pneumonia had developed.

Five other rabbits inoculated intraspinously by lumbar puncture with ¼, ½, ¾ and 1 c.c. of a suspension of micrococcus R. recovered from the first inoculation and were consequently partially immunized when 7 to 21 days later they were inoculated with 1 c.c., and in one case with 2 c.c. of the suspension of micrococcus R. described above. After the second inoculation they acted like the six rabbits of the first group and died within 18 hours. One rabbit, No. 2, lived 2½ days and developed symptoms of ascending paralysis. Spasms of single or groups of muscles were not observed. One rabbit, No. 9, died during the second inoculation from the unskilled administration of ether which was used to induce general anesthesia. Pure cultures of the organism were obtained from the cerebrospinal fluid, the meninges, the substance of cord and brain and the heart blood of these five rabbits. The fibrinopurulent meningitis was more pronounced in the five rabbits of this series than in the six rabbits which died rapidly after the first inoculation. In the meninges there was a proliferation of fixed cells and more exudate over the posterior portion of the external surface of the pia. There was no surface exudate of the meninges of one rabbit of this group, No. 4. The degeneration

*Dr. Hiss has found that normal horse-serum acts on the meningococci. Normal saline may also do this. But in these tests normal horse-serum was not studied. The results were so sharply contrasted that further studies of this appeared unnecessary.

of brain and cord was similar to that of the first six rabbits, but there was in addition a dilatation of the central canal of the cord (a condition of hydromyelia). The viscera showed parenchymatous degeneration and necrosis.

To complete the study of the action of this organism in animals and in the hope of securing lesions of the type found in the cord of man, a monkey, macacus rhesus, was inoculated intraspinously with 3 c.c. of a 24-hour broth culture of micrococcus R. After inoculation the animal recovered immediately and sat quietly on the floor of its cage until five hours later when motor spasms, twitchings of the legs, were noticed. The next day the monkey had anorexia, fever, and was in stupor. The spinal fluid withdrawn by lumbar puncture was slightly turbid and the culture yielded a pure

FIG. 5—Section of spinal cord in lumbar region of rabbit No. 7 (high power). Fibrinopurulent meningitis; congested meningeal vessels with perivascular infiltration. *Lateral columns:* Destruction and liquefaction of nerve tissue. Reticulum of neuroglia is fragmentary in many places and in others liquefied. *Gray matter:* The structural character of the large motor cells is preserved. They are somewhat shrunken and show a decrease in the amount of chromatin. The lymphatic space around the anterior horn cells is markedly distended. *The central canal* is markedly dilated and shows a slight exfoliation of its lining.

growth of micrococcus R. In the stained smears the diplococcus was both intra- and extracellular. The following two days the monkey was sick, but there were no muscular twitchings. Five days after the first inoculation another lumbar puncture was made and ½ c.c. of cerebrospinal fluid withdrawn. From this only one colony of micrococcus R. was recovered. Then 7½ c.c. of a 24-hour broth culture of micrococcus R. were injected intraspinously. The monkey was prostrated after this injection, respiration was slow and labored, then rapid and shallow. It was lying on the floor of the cage with the neck stiff and retracted and the legs stretched away from the body. The monkey died 16½ hours after this second injection. No cerebrospinal fluid could be obtained by lumbar puncture Cultures taken with the platinum needle from the cauda equina during the autopsy gave a luxuriant and pure growth of the Gram negative micrococcus. The cord, which was congested, was prepared for celloidin sections.

Microscopical Examination of the Cord.—The meninges, pia, and arachnoid, were thickened posteriorly only by a proliferation of connective tissue. There was little fibrinopurulent exudate on the surface. The blood vessels were congested. The larger motor cells of the anterior horns appeared pale. Their nuclei were eccentric and some of them showed advanced chromotolysis. There was no increase of neurogliar tissue, nor was there any diminution in the number of cells. Some large cells were swollen and pale. The central canal was not dilated and its lining was intact. In the lateral columns small, white, round areas were found, especially toward the periphery. These were liquefied axis cylinders. The acute inflammatory changes were apparently due to the second inoculation and the thickening of the meninges from fixed cell proliferation to the first. Both organisms produced degenerative changes in the cord and brain but differed in regard to their action on the meninges. In rabbits micrococcus R. induced lesions similar to those of cerebrospinal meningitis in man; *Micrococcus intracellularis* of Weichselbaum did not give rise to these lesions in rabbits.*

Conclusion.—This organism isolated from the cord of a man who died of hemorrhagic myelomalacia is a micrococcus of a morphology similar to that of the *Micrococcus intracellularis* of Weichselbaum, save that under certain conditions it produces bacillary forms. It stains with ordinary dyes and is Gram-negative. It has no demonstrable capsule and forms no spores. It grows luxuriantly on all ordinary media whereas the growth of meningococcus of Weichselbaum is often scanty. On glucose-agar its growth is more slimy and vivid than that of *Micrococcus intracellularis* of Weichselbaum. Like the meningococcus it produces no gas, no indol, is aërobic and does not liquefy gelatin. It ferments and coagulates dextrose and galactose blood-serum-litmus-water. The meningococcus of Weichselbaum ferments dextrose and maltose and sometimes levulose without coagulation. It grows at room temperature and has been kept alive in the ice box for 1½ years. The "strain Fraymann" of meningococcus of Weichselbaum grows also at room temperature but lives in the ice box only nine days. In the dry state it was kept alive for eleven days, while the meningococcus lived only five days. Its thermal death point is 64° C. in 10 minutes and 60° C. in 75 minutes. Flexner states that the meningococcus of Weichselbaum is killed in 60° C. in 30 minutes. It is not agglutinated by a monovalent nor polyvalent antimeningococcus serum, nor by the serum of *Micrococcus catarrhalis* and of *Micrococcus mucosus capsulatus.* It thrives exceedingly well on the cerebrospinal fluid and in the substance of brain and cord, giving rise to an exudative inflammation of the meninges and an acute and very rapid degeneration, and necrosis of the nerve cells and their processes in man and laboratory animals. *Micrococcus intracellularis* of Weichselbaum produces degenerative changes in cord and brain of man and laboratory animals and a fibrinopurulent meningitis in man and monkeys but not in rabbits.

*Flexner and others, except Petterson, also failed to secure lesions experimentally in rabbits with the meningococcus of Weichselbaum.

I desire to acknowledge my indebtedness to Dr. P. H. Hiss and to Dr. Augustus Wadsworth for their advice and help in preparing this paper.

THE RELATION OF BACTERIAL METABOLISM TO CERTAIN FOODS.*

By ARTHUR I. KENDALL, Ph.D., Dr. P. H.

CHICAGO, ILLS.

The inauguration of the Pure Food and Drugs Act provided the American people with a mechanism for regulating, in theory at least, the production and sale of wholesome food. The law, as it is interpreted at the present time, however, appears to regard sophistication and adulteration rather than the purely health side of the problem as its chief province. The wholesomeness of foods is judged rather by the absence of adulterants and substitutes than by the recognition of those factors which make foods actually dangerous to health. This interpretation has been satisfactory in the great majority of cases so far, but a group of foods has recently been brought into prominence (and instances of this sort will undoubtedly occur with increasing frequence in the future) in which the somewhat arbitrary chemical and bacteriological standards in use at the present time will fail to establish the correct interpretation of the situation and the spirit and the letter of the law will come in to apparently open conflict. So far as the purely chemical aspect of the subject is concerned this is unlikely to happen unless unusual substances, difficult to recognize by the methods customarily employed, escape detection for brief periods. Chemical sophistication and adulteration do not, as a a rule, result in progressive changes in the composition of foods and the detection of chemically unfit foods does not involve the time factor.

*From the Department of Bacteriology, Northwestern University Medical School.

Bacteriologically the case is somewhat different. Perfectly wholesome foods may be prepared and sold in an apparently sound condition, and yet contain within themselves the elements of their own destruction in the form of included bacteria. The development of these bacteria may bring into play an entirely new set of factors; factors which in time may modify profoundly the fitness of foods from the public health viewpoint, without altering the legal status of the case as it is interpreted according to present-day standards. The question of bacterial metabolism, particularly as it is related to the proteins and carbohydrates, enters largely into the solution of problems of this nature, since proteins and carbohydrates or their derivatives are the most common and important constituents of food stuffs in which bacterial development plays a part. The nature of the products formed by bacteria, even of the same variety of bacterium, is influenced profoundly by the presence or absence of utilizable carbohydrate. It is possible, for example, for a purely protein food to be so changed through the growth of bacteria in it as to be not only disagreeable to the senses, but actually unfit for human consumption. The very simple expedient of adding certain sugars to this same food may so modify the action of the bacteria upon it that the protein constituent is not measurably changed, even after considerable bacterial development. The products formed by this bacterial development may now be quite innocuous and inoffensive, and such food could be eaten with impunity. In other words the changes which take place in such foods are usually due to the results of bacterial growth, not to forces inherent in the foods themselves. Inasmuch as bacterial growth is the essential factor in the process, it is imperative that a knowledge of the nature of bacterial metabolism be considered in the interpretation of the phenomena involved. A few well-known experiments illustrative of bacterial metabolism, as it is related to the utilization of protein and carbohydrate will make clear at least the underlying principles; the actual problems to be solved in practice will vary in complexity with the kinds and number of bacteria involved and the composition of the food stuffs.

It is a well known fact that *B. coli* grown in media containing only protein or protein derivatives will produce indol, phenol, hydrogen sulphide, ammonia, and other products indicative of protein decomposition. The action of the organisms is of necessity restricted wholly to the utilization of protein substances. The reaction of the medium becomes progressively alkaline, foul odors develop, and the resulting products are not only disagreeable to the senses—they quite unfit such material for food. This is bacterial putrefaction. The same organism in the same protein medium, containing in addition sugar which the colon bacillus can utilize now produces an entirely different kind of decomposition; in place of indol, phenol, and hydrogen sulphide, there now appear lactic acid, smaller amounts of other fatty acids, as well as carbon dioxide and hydrogen, which are characteristic of the breakdown of carbohydrate by *B. coli*. The reaction now becomes permanently and progressively acid; the odor not unappetizing rather than otherwise, and the products formed are innocuous and inoffensive. This is bacterial fermentation. It will be remembered that the protein content is the same in the two experiments; the addition of sugar to the medium has brought about this vast difference in

the end products of bacterial growth. The sugar has been attacked by *B. coli* in preference to the protein, and in this sense has shielded the protein from bacterial action. Similarly, physiologists have long known that carbohydrate shields body protein in man.[1]

Examples illustrative of this shielding action of carbohydrate for protein might be cited from many fields of bacterial activity.[2] One of the most remarkable of these is that exhibited by the diphtheria bacillus. In sugar-free media this organism produces a powerful extracellular toxin; the same organism does not produce toxin in the same broth containing dextrose.[3]

Returning again to *B. coli*, this very preference which the organism exhibits for sugars is unconsciously but invariably taken advantage of in the cultural identification of the organism, and it might be added that this is a very general bacteriological procedure, applicable to the cultural identification of many bacteria. Bacteria are examined for their "fermenting" power in precisely this same manner, and the principle underlying this mode of cultural diagnosis is the sparing action which utilizable carbohydrate exhibits for protein when both are simultaneously present in the same medium. That is to say, bacteria as we know them appear to prefer carbohydrate to protein and this is simply a question of economy in the last analysis; carbohydrates are more easily metabolized than protein. This is not the whole story, however. Notwithstanding the fact that bacteria prefer utilizable carbohydrate to protein, some protein is broken down even when carbohydrates are being thus utilized by them. This follows directly from the fact that bacteria in common with all known living things, contains nitrogen in their bodies, consequently they must have some nitrogen in their dietary. There is no nitrogen in carbohydrate. This leads to a very important distiction which must be made between two entirely distinct factors of life processes in general, the structural (anabolic) and the vegetative (catabolic). These may be illustrated somewhat crudely by likening the requirement of living things (bacteria in this intsance) to those of a locomotive. A locomotive is built of iron and steel; it is run on coal and water. The structural requirement (and the waste incidental to loss of parts which must be replaced) can be satisfied only in terms of iron and steel. The fuel requirement, on the contrary, can be satisfied only in terms of water and coal. Furthermore, the fuel requirement is not fixed, but continues during the life of the locomotive as a steady and continuous drain which must be continually replaced so long as the engine runs. The structural requirement, it will be seen, is relatively small and the fuel requirement relatively great.

Similarly, the structural requirement of bacteria must be obtained, in part at least, from material containing nitrogen, and precisely as the structural requirement of the locomotive is complete aside from wear and tear when the machine is completed, so the bacterial structural rquirement is complete, aside from losses incidental to the excretion of ferments, etc., when the organism is formed. In both instances the structural requirement is very small in comparison to the fuel requirements. The structural requirement of bacteria, therefore, presupposes at last minimal amounts of nitrogen in utilizable form, which they usually obtain from protein or protein derivatives. The fuel requirement, however, can be presented to them either as nitrogenous compounds (protein or protein derivatives) or as utilizable sugars. Whenever bacteria are presented simultaneously with protein and utilizable carbohydrate in the same medium, the structural needs are largely derived from protein, the fuel requirements from the sugars. The actual structural requirement of bacteria is very little. *B. coli* is an average sized bacillus. It is about 1 micron (0.001 millimetre) in diameter, and about 2 microns long. Its volume, assuming that the organism is a rectangular prism of the dimensions given instead of a cylinder, would be 0.001 x 0.001 x 0.002 millimetres, or 0.000,000,002 cubic millimetres. The weight of the organism similarly, assuming that its specific gravity is that of water (it is estimated to be 1.38), is 0.000,000,002 milligrams. At least 85 per cent. of this weight is water, hence the actual amount of material other than water in a single colon bacillus is very little. Five thousand million colon bacilli would weigh about one milligram. It is practically possible to measure with considerable accuracy the relative amounts of protein broken down to satisfy both the structural and the fuel needs of bacteria growing in ordinary media. It is also possible to measure by similar procedures the extent of the sparing action which utilizable carbohydrate exercises for protein. This is best accomplished by determining the increase in ammonia content of media incidental to the growth of bacteria in them. For this purpose broths with and without sugar, but otherwise of exactly the same composition, are used. The ammonia content is measured conveniently and accurately according to the methods recently elaborated by Folin and his co-workers.[4] Analyses made in accordanace with these methods show that *B. coli* produces about 2 milligrams of ammonia above that of uninoculated controls in 100 cubic centimetres of broth containing dextrose and protein.[5] *B. coli* produces about 20 milligrams of ammonia above the inoculated controls *in the same protein broth, but without the dextrose;* in sugar-free broth in other words. By actual count the sugar-free broth contained about 2,000,000,000 living organisms per cubic centimeter at the end of six days, while the sugar broth contained 1,200,000,000 living colon bacilli under the same conditions. It is obvious that the observed differences in ammonia production (protein decomposition) are not attributable to unequal development of bacteria, but rather to an actual change in the nature of the metabolism of the bacteria themselves. The bacteria have acted upon sugar in preference to the protein, deriving their fuel from the sugar. That is to say, the addition of the sugar has prevented 90 per cent. of the protein breakdown as measured by the ammonia standard in the experiments quoted. It is worthy of note that the sugar broth was decidedly acid in reaction at the end of the experiment (six days) and that the dextrose had been more than half used up. The sugar broth, furthermore, contained no indol, hydrogen sulphide, or other products of protein breakdown, at least in detectible amounts. The small amount of ammonia produced in this sugar broth is a fairly reliable index of protein breakdown for structural purposes. The plain, sugar-free broth, on the contrary, was alkaline in reaction, and contained ten times as much ammonia, indicating a much more extensive and deep-seated protein breakdown. Indol, hydrogen sulphide, and phenols were present in large amounts.

A situation which involved these same general

principles has recently been brought to the public attention. This is the so-called Trenton egg case. The facts brought out at the trial were essentially as follows: Certain cases of frozen eggs containing 10 per cent. of sugar (sucrose) were seized by the government because they contained from ten thousand to ten million *B. coli* per gram egg. These eggs were pronounced decomposed because they were heavily infected with bacteria. These bacteria, furthermore, were stated to be colon bacilli, which are characteristic of the excrement of man and the higher animals. The case appears to have been tried purely on the grounds that the eggs were "decomposed" and because of this decomposition they were seized under the Pure Food and Drug Act. No other bacteria than *B. coli,* either pathogenic or otherwise, were specifically designated as possible agents of decomposition, nor was the added sugar mentioned (prominently at least) as an adulterant; the whole issue appears to have hinged on the question of decomposition in these sugared eggs, brought about apparently by the extensive development in them of large numbers of bacteria of fecal origin, specifically *B. coli.*

The regular standard for eggs as adopted by the government stated that eggs shall contain no more than one million bacteria per gram egg, of which not more than one thousand shall be colon bacilli. A bacterial content in excess of this standard constitutes a legal basis for seizure. It should be stated that considerable latitude in the number of bacteria is allowed in cases of this kind, because the unavoidable error of sampling and counting renders bacterial determinations somewhat inaccurate.

It might appear at first sight that fresh eggs should be quite sterile, for their contents are protected by a shell which is lined internally by a definite membrane. Many years ago Schottelius and others noticed that sterile eggs were extremely difficult to obtain, and certain testimony presented at the Trenton trial indicated that the anatomy of the hen was such that bacteria may be included in the egg contents before the shell is secreted around it; among these bacteria colon bacilli may be found at times in moderate numbers.

The eggs concerned in this controversy exceeded greatly the legal limit in bacterial content, and at first sight this seizure might seem warranted, particularly in the light of the large number of fecal organisms of the colon type. Certain other features, however, complicated the situation. These eggs appear to have contained no frankly pathogenic bacteria (colon bacilli are habitually present in the intestinal tract of man and no evidence was produced to show that these colon bacilli differ from the human type), hence their seizure was made on the grounds that they were "decomposed," implying thereby that either the included bacteria or some other unspecified factor had so changed them that they were no longer fit for human consumption.

The question of the fitness of the eggs for human consumption was apparently eliminated from the discussion, for they were actually introduced in court, cooked in cake and pastry and eaten there without the slightest objectional taste or odor being demonstrable. The culinary products, of which they formed a part, were undistinguishable in taste and odor from similar products prepared from eggs of known freshness. At a hearing subsequent to the trial, the whole issue was finally reduced to the question—are these sugared eggs decomposed? The health side of the problem was eliminated by the district attorney before whom the hearing was presented; he ruled that the defendants could attempt to show that the eggs were not decomposed, they could not show that the eggs in question were fit for human consumption. At the trial it was shown chemically that the eggs in question were not decomposed when judged by either qualitative or quantitative standards, in spite or the high bacterial content. They contained no indol, hydrogen sulphide, or phenol (which are indicative of protein breakdown by colon bacilli), and no more ammonia than eggs of known freshness.

Strictly fresh eggs contain no indol, hydrogen sulphide, phenols, and but little ammonia; the amount of ammonia in strictly fresh eggs according to the testimony submitted varies from two to four milligrams per one hundred grams egg. The "sugared eggs" contained 3.18 milligrams of ammonia per one hundred grams egg according to the following table:

Bacteria per gram egg.	Ammonia per 100 grams egg.
26,000,000	2.88
31,000,000	3.39
23,000,000	3.18
10,000,000	2.86
22,000,000	3.60
30,000,000	3.47

This leads to a somewhat paradoxical situation. Certain cans of frozen eggs containing 10 per cent. of sugar greatly exceed the legal permissible bacterial content. They are seized because they are said to be decomposed. The most refined chemical methods available at the present time failed to detect either quantitatively or qualitatively any measurable decomposition in spite of this large bacterial content.

How, then, reconcile these very widely divergent results, undoubted immense bacterial content on the one hand and negative chemical evidence on the other hand, indicating apparently the absence of bacterial decomposition of these eggs; in other words, how explain an extensive bacterial growth and no measurable chemical evidence of this growth? Everyone is familiar with the fact that at times unsugared eggs contain undoubted qualitative evidence of bacterial decomposition!

Confining this discussion strictly to the evidence produced at the trial, two features are very apparent. The chemical evidence, so far as it went, was very direct and convincing; the bacterial evidence was correct so far as the number of bacteria were concerned, but it failed utterly to take into account the real factor involved, the shifting of the metabolism of *B. coli* through the action of the added sugar; these organisms apparently were of the sucrose-fermenting type (which is somewhat surprising, for the non-sucrose-fermenting type is the one commonly met with); they acted upon the sugar in preference to the protein (nitrogen-containing) constituents. As a matter of fact these eggs were shown to be more acid in reaction than fresh eggs; this acidity is not only easily accounted for, it actually would of necessity be present if colon bacilli (in the absence of other bacteria) were utilizing it for catabolic needs. In the light of the studies mentioned above on the metabolism of *B. coli,* then, the facts brought out at this Trenton egg case trial are simply and directly explained; a large overgrowth of colon bacilli has taken place in sugared eggs which do not show a measurable amount of proteolysis to correspond to this excessive bac-

terial development. The slight increase in acidity together with the negative chemical evidence of proteolysis are in harmony with the observed facts. These colon bacilli have derived their "fuel energy," which is the conspicuous factor in bacterial decomposition, from the sucrose; producing thereby lactic acid, which is not found in strictly normal eggs. They have derived their "structural" requirements from nitrogenous products, as all living things must do. The waste from this structural requirement is inconspicuous and may be so slight as to escape detection, as appears to have been the case in this controversy.

It must be stated that as clean cut a case as this Trenton egg case should be regarded as an exception rather than the rule; ordinarily a varied bacterial population would be predicted in as cosmopolitan a medium as these eggs must have been. A varied bacterial flora would introduce additional complications, which would in turn involve bacterial symbiotic activity, a field but little touched upon at the present time.

There is an economic side to problems involving bacterial metabolism as an issue; in the Trenton egg case it is almost certain that the evidence presented at the trial would warrant the utilization of the sugared eggs for food, provided they were used as they were supposed to be, in culinary products cooked before being eaten. This presupposes that no additional contamination be introduced by the baker, a point beyond the control of the producer or the government.

The practice of adding sugar to these second grade eggs, freezing them, and shipping them in a frozen condition to bakers, appears to have been practised for some years. It theoretically makes a certain amount of material available which otherwise would have to be replaced by eggs of greater value, thus adding to the cost of the finished product of which they are an integral part. Just how important economically this process is cannot be stated by the writer.

It did not appear at the trial just why the sucrose was added to these eggs; if the preservative action of carbohydrate is the desired end, the sugar being introduced to restrict nitrogenous breakdown by bacteria, dextrose would be the sugar indicated, for the majority of bacteria utilize dextrose, while only a very few act upon sucrose.

It should be stated that cane sugar is used very largely in certain classes of preserves, usually fruits, usually in 10 per cent. concentration. The physical factor of osmotic pressure plays a part here for the sugar is dissolved in practically an aqueous medium and sugar of this concentration plasmolyzes many forms of bacteria, preventing, or at least, tending to inhibit their development. Spores do not germinate readily in such a medium. The addition of 10 per cent. sucrose to eggs would not prevent bacterial development to any degree, for the osmotic pressure of sugar in a colloidal egg solution is comparatively little.

If, on the contrary, sugar is added and sold at "egg prices," the procedure is a pernicious one; the relatively slight gain in preservative properties is far outweighed by the increase in cost of the mixture.

It is a remarkable fact that freezing does not decrease markedly the bacterial content of these eggs; the relative absence of water probably accounts for this phenomenon. Bacteria frozen in water die out rapidly; in colloidal solutions, such as egg, survive. The mechanical factor of ice crystal formation may well play a part in reducing the number of surviving organisms.

THE BENEFICIAL EFFECT OF DUODENAL ALIMENTATION IN CIRRHOSIS OF THE LIVER.*

By MAX EINHORN, M.D.,

NEW YORK.

PROFESSOR OF MEDICINE AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

At first sight it appears rather surprising that duodenal alimentation should be used in diseases of the liver. If we, however, consider the intimate connection of this organ with the digestive apparatus, we may expect that the rest given to the stomach may have some bearing upon its neighboring organ, the liver. The reason of this plan of treatment lies in the following consideration:

The function of the liver consists principally in keeping control over all the substances introduced by the act of digestion, excepting that part taken up by the lymphatics, before they reach the general

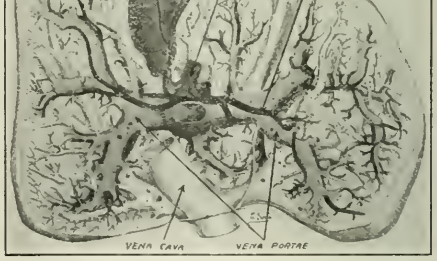

Diagram of liver showing blood vessels and bile ducts (after Bourgery, Poirier, Charpy et Cunéo, Abrégé d'Anatomie, 1909, p. 1308): Hepatic Artery, black; Portal Vein, light gray; Bile Passages, dark gray; Vena Cava, white. Note the enormous disproportion between the volume of the Hepatic Artery and that of the liver, the Portal Vein serving as a functional vessel.

blood stream. This is accomplished by the great network of the portal vein (see Illustration) which collects the outflowing blood from the entire digestive system and diffuses it for its elaboration in the liver. If the latter organ is diseased, its function of working up the portal blood and making it fit for the vena cava is slackened. What now happens is either the entrance of faulty metabolic products into the circulation, or, if the supervision of the liver is still efficient but slow, an accumulation of blood in the liver, i. e., this organ becomes unable to work up all the blood flowing in during the act of digestion. The organ becomes temporarily swollen. In some instances both factors coexist.

*Read before the American Gastroenterological Association at Washington, D. C., May 5, 1913.

In cirrhosis of the liver this difficulty of its function is always present. It leads to an enlargement of the organ and ultimately to ascites. In duodenal alimentation the upper part of the digestive system is not working and kept at rest. The venous circulation there is not very active. The portal vein is thus freed of part of its blood supply and the entire amount of work of the liver is thus made easier.

Duodenal alimentation was applied in six cases of beginning cirrhosis. In five there were gastric ulcers present; in one pure cirrhosis with dilatation of the heart. I shall describe three of these cases which may serve as illustrations:

Case I.—January 7, 1913. Mr. P. D., Jr., 31 years old, had inflammation of the bowels when eleven years old, then felt well until three years ago. At that time he began to suffer from pains in the upper part of the abdomen, which at times were severe, but usually mild in character. About four months ago patient was seized with pains in the ileocoecal region, accompanied by chilly sensations and fever. Several physicians advised an operation for the removal of the appendix, which was refused by patient. These pains in the abdomen, with slight rises in temperature, practically continued until patient consulted me. Patient complains of severe pains over the entire abdomen. The pains have no distinct relation to food. He occasionally vomits, particularly after a large meal or after the ingestion of eggs. There was no blood in the vomited matter. He feels bloated and frequently brings up gas. The bowels are very irregular and inclined toward diarrhea. Patient has lost considerably in strength and flesh. Patient admits of having indulged to a high degree in alcohol and tobacco. The physical examination reveals tenderness over the gastric region and all along the colon. The slightest pressure over the epigastrium elicits considerable pain. The liver is greatly enlarged. It can be discovered by palpation and percussion in the right mammillary line three fingers below the border of the ribs. The urine contains over 1 per cent. sugar, no albumin or bile. Temperature 100½ by mouth. There exist general malaise, extreme nausea, and pains in the abdomen after eating. The gastric contents after a test breakfast examination showed: HCl + acidity = 48; much mucus present; blood present. The duodenal bucket showed a permeable pylorus and a probable ulcer along the lesser curvature of the stomach (blood stain 17-19 inches, bile stain 24-31 inches). The blood count was: Red blood cells, 4,350,000; white blood cells, 13,800.

The diagnosis of gastric catarrh with ulceration and hypertrophic cirrhosis of the liver with probable involvement of the pancreas was made and duodenal feeding was instituted on January 13, 1913. The duodenal contents showed the presence of all pancreatic ferments: amylopsin, + 4 mm.; trypsin, + 3 mm.; steapsin, + 10 mm. Patient felt very comfortable during the period of duodenal alimentation. The pains subsided and there was normal temperature. One week after this treatment the liver was only one finger below the margin of the ribs, and after two weeks' treatment the liver could not be palpated. The sugar likewise disappeared from the urine. Patient made a good recovery and his liver has remained in good condition up to the present.

Case II.—Thomas J., 47 years old, admitted to the Post-Graduate Hospital March 15, 1913. Family history: Mother died of cancer of the stomach. Personal history: Works as laborer; heavy smoker for many years; up to three months ago has taken regularly two to three glasses of beer daily, whisky once or twice a week. History of bronchial asthma for past 18 years. Has had more or less disturbance of stomach for last five years, though he has not sought medical aid for it. In September, 1912, had sudden attack of pain and vomiting, in which a large quantity (one quart) of bright blood was vomited. Following this he was removed to a hospital and treated for four weeks, and discharged improved. His condition remained satisfactory for about one month, when he had a return of gastric disturbances. Since November, 1912, he has complained of distress in stomach almost constantly, with belching and feeling of nausea. Food aggravates the condition and brings on nausea: has vomited once a week; vomitus consisting of mucus, with no food remnants. In February, 1913, vomitus contained blood on two or three occasions, and he sought medical attention. Since then he has complained of severe distress in the stomach, belching, constipation, and general weakness. Since November, 1912, he has lost 22 pounds in weight.

Examination on admission to the Post-Graduate Hospital March 15, 1913: Chest: prolonged breathing and sibilant and sonorous râles on both sides. Heart: no murmurs present. Abdomen: upper border of liver begins at fifth rib in mammillary line; lower border two inches above umbilicus, edge blunt and free. Blood examination: red cells, 4,160,000; white cells, 4,000; hemoglobin, 90 per cent. Urine examination: S. G. 1.016; reaction acid; albumin negative; sugar negative. Examination of duodenal contents: contents alkaline; bile present; steapsin absent; trypsin present, 2 mm.; amylopsin present, 4 mm. Examination with duodenal bucket: no blood stain. Duodenal feeding was begun March 16, 1913. Patient is given every two hours milk, lactose, and one egg. Medication: atropine sulphate, grain 1/80, b.i.d.; magnesia usta and bismuth subnitrate. Patient was in bed from March 15 until March 21, when he was allowed to be up and feed himself. Examination of the liver March 28, 1913, shows upper border normal, lower border in mammillary line one inch below ribs, lower border in median line not palpable. Weight on discharge, 143¾ pounds. April 11, 1913: patient has gained six pounds in weight since leaving the hospital. Liver shows normal conditions, not being palpable nor discoverable by percussion in the right mammillary line below the margin of the ribs.

Case III.—February 18, 1913. John W., 57 years old, clerk, had scarlet fever when a child, rheumatism in Mexico about 22 years ago, also at same time malaria and dysentery. There is no syphilitic history. Since two and one-half years he complains of attacks of shortness of breath, not dependent upon exertion. He noticed at times edema of legs; there is no pain. Patient has been for years in the habit of taking a good quantity of beer daily, except for the last two years, when he did not drink anything.

Status præsens: Patient well nourished. Lungs negative. Heart: Apex beat felt in mammillary line in sixth interspace. Heart somewhat enlarged to the left. Systolic murmur present at apex, transmitted upward. Neither pulmonary nor aortic sound accentuated. Liver reaches in median line to within one and one-half fingers' width above navel and is easily palpable. It extends to the left mammillary line. Otherwise abdomen is negative. The urine shows a specific gravity of 1.014, the presence of albumin (0.025 per cent.) with occasional granular casts. Blood pressure 195 mm. Examination of stomach contents shows subacidity (HCl = 8; total acidity = 30) and presence of blood. February 19, 1913: Duodenal pump was given in the afternoon and left in for two weeks for duodenal alimentation. At the end of the first week of this mode of treatment the liver shrank so that it reached only to three inches above the umbilicus. The shortness of breath has entirely disappeared. Blood pressure was 185 mm.; then patient ate several hearty meals and his liver again returned to the size that it was on admission.

Summary: During duodenal alimentation in all the six patients the liver became markedly smaller (already after two to three days), assuming a size almost normal. In four patients the result was lasting. In one, however, a few days after the termination of the feeding the liver began to grow larger, while in another patient (J. W.) with pure cirrhosis and dilated heart the size of the liver quickly assumed its original large proportions. The influence of duodenal feeding was in this case very marked but not lasting.

My experience up to the present time justifies me in the conclusion that duodenal alimentation contributes greatly toward diminution of the functional work of the liver. This rest treatment of the latter organ is of benefit whenever it is considerably impaired. The cirrhoses of the liver and allied conditions, accompanied principally by swelling of the hepatic tissues, form a field in which duodenal alimentation may be applied apparently to great advantage.

THE DIAGNOSIS AND PROGNOSIS OF DUODENAL ULCER.*

By JAMES TAFT PILCHER,

BROOKLYN, N. Y.

Reports of recent society proceedings and various periodicals have contained so many communications upon this subject that one might imagine it by now quite devoid of other than historical interest, yet the writer believes that a more careful consideration will show that thus far only a few of the more salient facts relevant to the disease have been outlined.

The history of an uncomplicated duodenal ulcer, as obtained from some two hundred cases personally observed, has in the great majority of them elicited four pre-eminent factors: First, the *chronicity* of the complaint; second, the *periodicity* of the exacerbations of epigastric distress; third, the occurrence of *pain* of a peculiar character with precise time of onset; and fourth, the *control* of this discomfort by the ingestion of food or alkalies.

The average duration of the complaint in the earlier cases was well over ten years, while it is encouraging to note that lately this long period has been markedly reduced, owing without doubt to our growing familiarity with the condition and its symptomatology.

Indeed, one should seldom, with our present knowledge of duodenal ulcer, be led astray in the diagnosis of the patient, usually male, who remarks that in the beginning of his trouble he noticed the onset of pain or burning in the pit of the stomach accompanied by sour eructations, belching and possibly regurgitation at times of small quantities of acrid material, frequently termed *water brash*, which condition at first lasted from a few days to several weeks, when suddenly, whether without medication or in spite of it, his distress ceased, and was followed by a varying interval of complete health, when the same syndrome was repeated. In many cases probably the interval of relief was not so complete and he merely had his good and bad days, with exacerbations at varying intervals of time. Either of these phases may continue for years, but finally the periods of remission become shorter and those of distress longer, until a stage is reached when there may not be complete relief at any time. Such an anamnesis is in itself sufficient to warrant the examiner in forming a tentative diagnosis, at least, of a duodenal ulceration. It typifies well the factors of chronicity and periodicity previously referred to.

Possibly, however, the most corroborative subjective symptom to be elicited is the peculiar effect that ingestion of food has on the epigastric distress, which act will almost without exception be found to give immediate relief, at least in the earlier stages of the condition before complications have arisen. We have been able to show experimentally that the reason for this phenomenon is because the mechanical stimulus thus given to the stomach excites a reflex flow of the alkaline duodenal secretion which thus neutralizes the irritating hydrochloric acid present in the duodenum.

The pain complained of is usually characterized as a burning or gnawing, frequntly as an intense hunger, amounting to an actual ache. One also hears it described as an "all gone" sensation.

Its character remains fairly constant until the chronic thickening has produced a moderate stenosis or crippling adhesions have formed involving the gall-bladder or other adjacent structures. The most important point regarding the pain, however, is to ascertain the time of its occurrence, which averages usually between two and one-half to four hours after meals. This time element recurs with the most remarkable precision and exactitude; and while differing in different patients, practically never changes in an individual case until other processes are engrafted on the original lesion. We have noted that the nearer the pylorus the ulceration is the earlier seems to be the onset of the distress.

We must also realize that we have in the duodenum two distinct pathological processes to deal with. It is to be noted that ulcers on the anterior superior surface differ very markedly in character from those on the posterior wall, in that the former as a rule have a very slight defect of the mucous membrane, in no way corresponding to the area of infiltration felt from the outside, the orifice seldom exceeding the size of a B.B. shot, frequently being recognized as a mere slit; while those on the posterior wall approach in character the typical punched-out round gastric ulcer. The latter seem to perforate rapidly through the several coats of the intestine and are usually found to have their base formed by the pancreas which is frequently deeply invaded by them. The surgical significance which these different pathological processes offer has been lately pointed out admirably by W. J. Mayo.

The variation in the symptomatology evidenced by these two types of duodenal ulceration offers also to the diagnostician further data for differential diagnosis, since in analyzing carefully the series forming the basis of these remarks it was noted that those cases showing the callous round posterior ulcer gave much longer histories, were not so acute in the differentiation of the cardinal diagnostic factors, did not suffer so much acute distress, but complained of a more continued discomfort which in turn was not affected so definitely by the intake of food and usually caused the maximum of duodenal deformity, and, consequently, the greater degrees of stenosis. Further, they are much more easily demonstrable in a radiograph, while the anterior small ulcerations evidenced the more typical syndrome, seldom caused much deformity or stenosis, usually bled more easily, continuously and freely, and were seldom diagnosticated by *x*-ray.

There have been many accessory aids to the diagnosis of duodenal ulcer heralded from time to time. Of these the *x*-ray is undoubtedly the most important, and when plates are obtained showing constant and unchanging deformity of the pyloric cap, one is safe in assuming that there must be present some factor causing a disturbance of the muscular functions of the parts, and this, if adhesions can be excluded, is in most probability an ulcer. But the writer feels that the greater one's experience is with *x*-ray examinations the less he believes the examiner will be apt to base too positive a diagnosis on the findings thus procured, other than in a corroborative sense.

Gastric analysis shows us that there exists in a great majority of cases a definite hyperacidity. This, however, is found in many other intraabdominal conditions other than duodenal ulcer, which likewise reflexly stimulate the gastric secretion. Its presence is very suggestive however, particularly

*Read before the Medical Society of the State of New York, April 30, 1913, at Rochester, N. Y.

if an analysis is also made during an interval free from distress, at which time we have repeatedly noted that the acidity of the stomach is usually normal and frequently subnormal.

Blood in the stools is another corroborative finding, but the factor of error, which is particularly unavoidable in ambulatory cases, is so great as to practically remove it from a position of any real diagnostic importance.

Corroborative evidence may also be obtained from the use of the string impregnation test, as to both the presence and cure of an ulceration. When one sees the various and bizarre forms and positions of these stomachs as portrayed by the radiographer, the more exact location of an ulcer by the aid of such a definite localizing procedure is always important.

Thus, one would think that, taking everything into consideration, the diagnosis of a duodenal ulceration should prove a relatively easy task, and it is in many cases. But the really important factor has as yet not been mentioned, viz., What has caused the ulceration?

In referring to the ulceration may we not at the same time classify it by prefixing a surname indicative of its etiological factor, suggestive likewise of an accessory symptomatology and the method to be employed to relieve the condition, whether treated medically or surgically? Thus the terminology, jejunal duodenal, ileocecal, appendical, colonic, membranous pericolitic, static, or ptotic duodenal ulcer might prove advantageous as well as instructive.

Many people undoubtedly carry about potential factors of an impending abdominal catastrophe without their ever being recognized, the symptoms being so mild that they have long since been disregarded by both themselves and their physicians. But in many of these cases we must feel that it is only the limitations of our diagnostic acumen, or possibly the defects in the proper examination, which allow them to slip by unrecognized, unsuspected, and improperly treated.

The prognosis in many instances is, of course, a relative question. Yet personal experiences with some fifteen acutely perforated ulcers of the duodenum and observations on a great many more chronically perforated cases certainly lead one to think that the consideration of repairing these conditions, either surgically or medically, is surely one of great importance.

The anterior ulcers are the ones that perforate most frequently. Such perforations are usually of the blown-out character. They are unfortunately the most frequent in occurrence and therefore lead one to make a rather unfavorable prognosis if such ulcers are allowed to continue their course. The posterior ulcers, on the other hand, seldom perforate into the abdominal cavity; but are prone to inaugurate complications which in the end may prove quite as dangerous as an acute perforation, namely, pancreatitis, common-duct obstruction, and duodenal stenosis.

The engrafting of carcinoma on the base of a duodenal ulcer is of so relatively rare occurrence that it may be disregarded.

In many instances the prognosis has to be determined by that of the etiological condition, as in death from a ruptured appendix in which a duodenal ulcer is found post-mortem.

Many patients enter into a state of chronic invalidism, if untreated, although the local condition remains unchanged. Notwithstanding the fact that the recurrent attacks have become more frequent and increased in their severity, the patient usually experiences a progressively lessening degree of relief from the measures previously employed with benefit.

Others, and this must represent a large class, suffer but slight discomfort, or none at all.

In our experience cases properly chosen for medical or surgical treatment appear to have remained fairly comfortable. Using them and reports from other clinics of cases similarly treated as criteria, one may be justified in saying that the prognosis in the very great majority of cases is good.

THE TREATMENT OF PERSISTENT OTORRHEA IN INFANTS AND YOUNG CHILDREN BY THE ESTABLISHMENT OF POSTAURICULAR DRAINAGE.*

A PRELIMINARY REPORT.

By WENDELL C. PHILLIPS, M.D.,

NEW YORK.

The term persistent otorrhea in infants and young children as herein employed, applies to those cases in which an acute purulent inflammatory process invades the middle ear spaces, and continues without abatement for an indeterminate period after the usual five to thirty days, which ordinarily may be considered as its normal course. This type of purulent otitis media should be differentiated from that other and rather common class, which may be termed recurrent, in which recovery may take place from each attack only to be followed by recurrence at varying intervals, usually as a result of an acute rhinitis. Children of the latter class are invariably the victims of hypertrophied tonsils and adenoids and their attacks usually cease upon the removal of these offending tissues. The recurrent type, therefore, is to be eliminated from this discussion, unless the otorrhea finally becomes persistent and chronic. A typical case of persistent otorrhea of the type under consideration presents a history somewhat as follows: Following some form of infection, which involves the upper air passages such as grip, the examthemata or pneumonia, an acute middle ear suppuration appears. Weakened by the primary general infection, the child's resistance is lowered and in many instances some underlying dyscrasia, known or unknown, adds its quota to the lowered resistance. From the outset, the discharge is profuse, persistent, and of a character which plainly bespeaks a severe type of infection. The usual diminution in quantity which in ordinary cases appears at from the third to the seventh day, does not take place, but the temperature becomes normal, or nearly so, pain is not present thereafter and there may be no marked drooping of the postero-superior canal wall. The usual local measures of treatment consisting of paracentesis, cleansing, cathartics and rest in bed may have been carried out in full, although in many instances, clinic patients have received no treatment at all.

It soon becomes evident that the small tympanic

*Read before the American Laryngological, Rhinological and Otological Society, Washington, D. C., May 8, 9, 10, 1913.

cavity proper could not secrete the amount of pus which flows from the ear, and one is forced to the conclusion that the additus and mastoid antrum at least must be involved. It is evident that such a discharge continued beyond about the third week furnishes evidence that the case is rapidly becoming chronic and calls for a different form of treatment.

It is true that proportionately a large number of persistent otorrheas are found among the poor and ill nourished which apply for hospital or dispensary treatment.

Of the underlying dyscrasias which almost invariably prevent nature's efforts, aided by efficient local treatment, from affecting a cure of acute purulent otitis media, tuberculosis and syphilis are the most stubborn to deal with and all writers agree that a considerable proportion of the chronic otorrheas are tuberculous in character. In these, local drainage from the membrana tympani does not seem to avail, and the disease progresses for long periods, and often with serious and fatal complications. Inanition from other causes is also a common cause of delayed cure. Severe types of infection, such as diphtheria, measles, pneumonia and grip are obstacles difficult to overcome. In many of the latter cases, however, there is a more or less rapid development of positive mastoid symptoms, hence, they are not to be considered in this discussion.

Treatment: Regarding the treatment, we do not advise any operative interference until all reasonable local measures have been faithfully carried out, this to include free drainage by paracentesis, a clean regimé of local treatment and attention to hygiene and the general health. In certain patients who are the victims of markedly hypertrophied tonsils and adenoids and the purulent otitis has progressed beyond the temperature stage, it may be wise to delay postauricular drainage for a short time and remove the tonsillar and adenoid masses. All these measures having failed, the question of surgical interference must be considered, and in the writer's opinion, the quickest, safest and most rational measure to pursue is to establish postauricular and, hence, through and through drainage by means of the simple mastoid operation.

The reasons are as follows: (1) It quickly terminates an otherwise persistent otorrhea. (2) It insures against an extension of local bone necrosis. (3) It prevents the case from becoming a chronic purulent otitis media, with all that the name implies regarding a chronic offensive discharge, loss of hearing, bone necrosis and possible serious and fatal complications. (4) Finally, the most important reason is, the restoration and retention of the hearing function.

It need not be added in this presence, that this operation is not a dangerous one, neither is its slight seriousness to be compared with the dangers and discomforts attending a chronic aural discharge.

In the considerable number of operations which have been performed by myself and assistants, I have been surprised at the frequency with which the pus escapes under pressure through the opening made into the mastoid antrum. Granulation tissue is also present, and in several cases an exposed sinus or dura has been found. These cases operated upon have complained of discharge for from six weeks to five years. In the more chronic ones, the simple mastoid operation has sometimes proven insufficient and the radical mastoid operation has become necessary. In a few cases, a similar procedure has been employed in adult patients, and one or two reports of these may come out in the discussion.

It may be stated, however, that in young children, when performed any time between four weeks and three months, that the results have been most favorable.

In a subsequent paper, I hope to give definite statistics of value. Others of our members no doubt hold the views herein outlined, and it is hoped that these somewhat desultory remarks may bring out a valuable discussion.

A CASE OF EXPLODED URETHRASCOPIC LAMP; REMOVAL OF FRAGMENTS WITHOUT OPERATION OR SUBSEQUENT SYMPTOMS OR SEQUELS.*

By VICTOR COX PEDERSEN, A.M., M.D.,

NEW YORK.

Prior to making a urethral application through a Chetwood urethrascope the lamp received a slight blow in falling, but on inspection showed no break of either wire or glass. The treatment was, therefore, instituted after testing the lamp satisfactorily. In a moment or two the light was extinguished,

Showing fragmented base of bulb and filament attached to the wire coiled in a circular form and having the three main fragments of the bulb in its center. The dark spots on the wire and each fragment are heavy furniture glue for attaching them to the paper.

and as no loose terminals could be detected it was assumed that the trouble was in the lamp itself. The lamp was therefore withdrawn from the telescope for inspection and to my surprise and alarm was found to consist only of the base of the glass bulb and part of the filament incorporated therein (as shown in the illustration) just distal to the black drop of glue behind the wire employed to attach it and the fragments of the bulb to the paper.

The question now arose as to how to find and remove the fragments without offense to the mucous membrane of the urethra or to the patient's sensibility. The telescope was fortunately a short one, so that I was enabled to proceed as follows: The lamp of the full length telescope was taken, illuminated, tested, and passed down the tube. It was noted that the fragments that seemed at first to be against the mucous membrane were really

*Report presented before the West Side Clinical Society of New York, June 12, 1913.

distal to it in the tube. Of this the proof was that as the second lamp reached and passed them they changed from illumination to occultation because they really lay about 1 c.m. from the mucous membrane. It was an easy matter to rotate the instrument so that the mucous membrane could everywhere be inspected for other fragments. When the absence of these was demonstrated the telescope was withdrawn and the fragments shaken from it, as shown in the picture within the circle made by the wire. When fitted together these three fragments completed the bulb with full accuracy so that no thought was given to any other pieces of importance. It is almost needless to add that no sequels whatever followed this accident.

The reason for publishing the case is to show the facility with which the diagnosis was in this case established that the fragments were not in the urethra but in the tube away from its surface. If one had passed instruments down the tube in the hope of recovering the fragments he might easily have failed and have poked them out of its mouth into the canal.

THE TREATMENT OF PROGRESSIVE CASES OF PULMONARY TUBERCULOSIS.*

By MARY E. LAPHAM, M.D.,

HIGHLANDS CAMP SANATORIUM, HIGHLANDS, N. C.

When a case of pulmonary tuberculosis does not recover even under the most favorable circumstances, we say that it is because the case is progressive. We know that all cases cannot recover even with the best climate, nursing, and medical advice, and we say that these failures are progressive cases. The progressive nature of a case may be recognized almost at the very start, but more often it is only after repeated recoveries and relapses that the hopelessness is admitted, and then we free ourselves from all responsibility by saying that a progressive case cannot be cured; that no stigma of incompetency can be ascribed to our efforts, because the failure was entirely due to the inability of the patient to fight.

This fatalistic, non-responsible attitude universally prevailed until Brauer[1] came to the rescue of this class of patients by using the method of artificial pneumothorax advocated by Forlanini in 1882. By filling the pleural cavity with nitrogen and compressing the lung until it could not expand, Brauer and his followers succeeded in reporting 40 per cent. of recoveries of the cases treated by this method. The 60 per cent. failures were somewhat due to inability to compress the lung because of pleural adhesions, which either made the injection of nitrogen impossible, or else held the surface of the lung out so that it could not be compressed. For these cases of inability to compress the lung by means of an artificial pneumothorax, Brauer considered whether the lung might not be kept from expanding by resecting portions of the ribs. He argued that if enough of the chest wall could be made to sink in and nullify the action of the inspiratory muscles, two results would be accomplished: first, there would be functional rest because the lung could not expand; second, when the pull on the surface of the lung did not exist, then the natural elasticity of the tissues would cause their retraction, they would draw close together and up toward the hilum, thus shrinking and reducing the size of all open spaces, whether normal or pathological. Into this shrunken lung air does not easily enter; there is stasis of the lymph and blood currents, the conditions are unfavorable for the development of tubercle bacilli; there is less production and absorption of toxins, the temperature drops, tubercle bacilli disappear; in short, the results are analogous to those obtained by an artificial pneumothorax.

Brauer was not the first to advise resection of the ribs. Quincke[2] in 1888 and Spengler[3] in 1890, and Turban[4] and Landerer[5] and others have resected portions of the ribs situated directly over cavities. Brauer was the first to see what a complete retraction of the lung would accomplish and that it could not be obtained unless the pull of the chest wall upon the surface of the lung was sufficiently destroyed. Brauer's ideas were carried out with great vigor by his colleague Friedrich,[6] who adopting the method used by Quénu and Tietz for empyemas, made a vertical incision in front and behind and resected the ribs between. This heroic operation obtains a collapse of the lung equal to that of an artificial pneumothorax, but its great severity and dangers make it impracticable. When well borne, the results were so astonishingly favorable that many efforts were made to obtain these results without the dangers.

Boiffin[7] simplified the undertaking immensely by making a paravertebral resection of three or four cm. of the first six or eight ribs. The sternal ends of the resected ribs fall in and press upon the surface of the lung, and the chest wall collapses and brings the sternal ends close up to and in under the vertebral stumps, thus lessening the size of the thorax and favoring the retraction of the lung.

Wilms[8] further improved this method by sectioning the costal cartilages at a later operation.

Sauerbruch[9] of Zürich was then an associate of Brauer's at Marburg. Comprehending Brauer's ideas for the necessity for functional rest and complete retraction of the lung, he extended the paravertebral resection to the tenth and eleventh ribs and by removing larger portions of the lower ribs gave the incision in its lowest part something the shape of a fishhook, so that this incision might be regarded as the posterior part of a Schede incision.

Sauerbruch's operation is the best yet proposed because while almost devoid of danger it obtains the most complete functional rest of the lung and its greatest retraction. It can be performed under local anesthesia in from 17 to 40 minutes, and if the patient's condition demands it the operation may be concluded at a later time, thus avoiding any overstrain upon the patient's endurance. We may advise resection of the ribs whenever the progressive nature of a case is admitted, and the lung cannot be compressed by an artificial pneumothorax. The advantages of an artificial pneumothorax give it the preference over resection of the ribs, but if it fails, then resection is our only recourse. Practically all of the resections made have been done for this reason, but there is one condition which in the future may lead to the choice of resection. When there is a cavity surrounded by a thick wall of adhesions, we cannot compress this cavity unless these adhesions are broken up. In attempting to force the separation of the pleural layers, there

*Read at the ninth annual meeting of the National Association for the Study and Prevention of Tuberculosis, Washington, May 7, 1913.

is danger of tearing the surface of the lung and causing an open pneumothorax, or of rupturing the walls of the cavity and causing empyema.

Volhard's report[10] well illustrates this danger. In these cases, a resection of the ribs would be safer than an artificial pneumothorax. In cases of incomplete artificial pneumothorax, when a portion of the lung is held out by adhesions and cannot be compressed, the force of the adhesions may be destroyed by resecting the ribs over them, and the rest of the lung compressed by nitrogen. In cavities of the lower lobe, when an artificial pneumothorax fails, a thorough resection of the lower ribs succeeds. In cases that have no money and cannot afford the time and expense of an artificial pneumothorax, the patient can get back to work more quickly.

The condition of the other lung, and the intestines and the larynx must be estimated just as we would for an artificial pneumothorax. The general condition must be better, and the heart stronger. The obliteration of an empyemic cavity is best accomplished by resecting the ribs first and then draining. In this way, the falling in of the chest wall abolishes the box-like cavity, approximates its walls, favors synechiæ, and forces out all secretions. Sauerbruch reports a brilliant success in a case of desperate pyopneumothorax.

In all, 90 progressive cases of pulmonary tuberculosis have been treated by resecting the ribs. Sauerbruch 43, Freidrich 29, Wilms 12, Landerer 6, Bang 3,[11] Delageniere 3,[12] Poppert 3, Turban, Spengler, Lenhartz,[13] Wolff,[14] Bier, and v. Mikuliz each 1. Out of 40 cases, Sauerbruch obtained 8 recoveries; 7 were markedly improved, and 4 of these will, in all probability, completely recover; 13 were improved, 6 of these 13 will probably improve more and possibly recover; 3 were unaffected, 4 declined rapidly, 1 died as a result of the operation.

Taking the deaths that occurred in a year after operating there was a mortality of 17.3 per cent. The recoveries were 20 per cent. By recovery is meant the persistency of working capacity for over a year after the operation, with no fever, no sputum, and absence of tubercle bacilli. Think of this: first, 40 per cent. of recoveries in progressive cases have been obtained by an artificial pneumothorax, and out of the 60 per cent. of failures 20 per cent. have been saved by resecting the ribs, under local anesthesia and through a single incision. Does this look as if the future of progressive cases was altogether hopeless? It may be that hereafter the recognition of the progressive nature of a case will be an essential, cardinal point in the treatment of pulmonary tuberculosis; that when a case does not improve under what the Germans call symptomatic treatment, we shall feel bound to make an effort to determine whether this inability to make or hold a recovery demands radical efforts. It may be that we shall hold a physician who allows his patient to drift on and on until he is past the help of operative influence, as equally culpable and responsible for the death of this patient, as we now hold the internist who does not recognize appendicitis or typhoid perforation, or mastoid abscess, or any other surgical condition demanding surgical aid. The recognition of the progressive nature of a case far from releasing us from responsibility, will add another burden, that of deciding what must be done and when.

We must first of all be able to realize when a patient is unable to make his own fight and then come to his relief; first, by attempting an artificial pneumothorax, and, if this fails, then by resecting the ribs.

Moreover, as Rochelt says,[11] it is not only the patient that will be benefited. When we remember that these hopeless cases nearly always have cavities, and that they produce and excrete an incalculable number of tubercle bacilli hourly, we can appreciate the value to the community of a relatively harmless and simple operation that destroys the production of these bacilli and converts a most dangerous source of infection into harmless sterility.

THE THYROID GLAND IN INFANCY.

PERHAPS there is nothing in medicine that is more interesting or that better shows how our knowledge has been brought together little by little than the history of our knowledge of the thyroid gland. Much that was learned became lost and had to be rediscovered. Conjecture upon conjecture was overturned to give way to beliefs a little nearer the truth. It shows that medicine has progressed aside from the laboratories which have to do with germs and parasites, and brings forth evidence very disconcerting to the antivivisectionist. As long ago as 1857 our scientific knowledge of the thyroid began when Schiff discovered the results which followed its removal and learned how to prevent these results by transplanting another thyroid gland into the peritoneal cavity of the animal. His work was soon forgotten and books continued to give for the existence of the gland explanations which now appear ridiculous. It was not until the late 70's that the "cretinoid state supervening in adults," as described by Gull, was discovered to be associated with atrophy of the thyroid gland. A few years later the surgeons recognized the chain of symptoms following total extirpation of the gland for goiter. Then it was that Sir Felix Semon pointed out that cretinism and myxedema of adults are identical and probably due to the same cause. This suggestion of Semon's was taken up in an organized investigation by the Clinical Society of London with Sir Victor Horsley in charge of the experimental work. He, quite independent of Schiff's long-forgotten work, recommended the grafting of thyroid as a method of treating myxedema in man. His suggestion was followed up by some surgeons and it was noted that the patients' condition improved immediately. It was this immediate occurrence of the improvement that led Murray to treat a myxedematous patient by hypodermic injections of an extract of the thyroid gland of a sheep. This proved to be a remarkable discovery and was soon enhanced by the further discovery by others that just as good results followed the administration of the extract by mouth.

At the same time that this good work was going on Gley rediscovered the parathyroid bodies which had been described ten years before by Sandström. It was because of ignorance of the physiology of these bodies that the surgery of the thyroid was unsuccessful for many years. From the results of experimental extirpation of the thyroid gland in animals it was held for a time that the thyroid was of less importance to herbivorous animals than to carnivorous animals. This was because one pair of the parathyroids in herbivorous animals is situated much lower and hence escaped removal. A wonderful amount of experimental work was carried on to learn more about the thyroid and parathyroids. All experimental work was soon somewhat checked, however, by the discovery of accessory thyroid gland tissue and accessory parathyroid bodies whose presence or absence could not be ascertained without an almost illimitable amount of work.

There is a recent contribution which may be turned to some practical advantage. S. Simpson (*Jour. of Exp. Physiol.* Vol. VI No. 2) has shown that age is an important factor in the effects which follow thyroidectomy and parathyroidectomy in the sheep. Simpson found that cretinism followed extirpation of the glands only in very young sheep. The practical bearing of this is that the thyroid is of the greatest importance during infancy and that if cretinism is to be properly treated it must be recognized early and treated immediately. His success in causing such well-marked cretinism is no doubt partly due to using lambs born of thyroidectomized ewes. There are many things which point to the relation of the thyroid to the reproductive system. In fact, in some of the lower forms of animals the probable analogue of the thyroid discharges its secretion directly into the uterus. Cretins are sterile. The reason why thyroidectomized animals may become pregnant is because of the accessory gland tissue or the well-known compensatory hypertrophy of similar tissue in the pituitary gland. The production of cretins of these lambs from thyroidectomized ewes recalls the heredity factor noted in Switzerland where goitrous parents are apt to beget cretins. This should serve to put us on our guard in observing the infants born of mothers with diseased thyroid glands. Cretins are rare, but if they are to be prevented treatment must be begun very early.

CRANIAL SURGERY, ANCIENT AND MODERN.

THE recent death of Dr. Hartley of New York deprived this country of one of the few surgeons who have helped to make America pre-eminent in the development of brain surgery. England, which has also made signal advances in this field, apparently acknowledges this supremacy. In the preface to his recent work on the surgery of the skull and brain, L. Bathe Rawling* states that he has been able to present the most modern aspects of the subject as the result of a visit to some of the leading surgical clinics of the United States. In

*"The Surgery of the Skull and Brain," by L. Bathe Rawling, F.R.C.S., Surgeon, with charge of Out-Patients, Senior Demoustrator of Practical Surgery, Demonstrator of Operative Surgery, St. Bartholomew's Hospital; late Hunterian Professor, etc. Price $6.00. Loudon: Henry Frowde, Oxford University Press: Hodder & Stoughton, 1912.

acknowledging this graceful compliment one must at the same time pay a tribute to the author's comprehensive grasp of his subject matter and to his skill in writing a work that bears the double imprint of scholarship and originality. The appearance of this work is timely, for the phenomenal achievements in the surgery of the brain and skull have mostly been made within recent years, and the literature recording them has been widely scattered in special journals.

Those who have kept in touch with this literature are probably familiar with the modern conceptions of craniocerebral topography, and with the newer technique and indications of operations on the skull and brain. It may suffice to recall that this progress has resulted in widening the scope and increasing the indications of these operations. A policy of inaction is no longer justified in the case of fractures of the skull, intracranial injuries, tumors of the brain, and infective diseases of the skull and brain.

The reproach has gone forth that many of those who have essayed operative work on the skull and brain have not been adept in surgical technique. Possibly this reproach has been justified so far as it concerned the activities of those who in their special work about the ear and to a less extent about the nose and its accessory sinuses have been compelled to deal with intracranial complications but who have not brought to bear upon this phase of their work the rigid demands of modern surgical asepsis and the newest technique. There can be no excuse nowadays for the inefficient preparation of the patient or the unskilful administration of the anesthetic. Rapidity of operation is no longer considered essential. It is surprising to note that Rawling prefers chloroform as the anesthetic, alleging that since it lowers the blood pressure there is less venous oozing, and that there is less liability to postoperative vomiting. American surgeons are not likely to substitute chloroform for ether, even though the risks of the former are diminished by expert administration.

Surgical maneuvers on the skull and brain have within recent years been greatly facilitated by the introduction of more efficient methods of hemostasis. The use of Cushing's or Rawling's scalp tourniquet, of Kredel's hemostatic sutures, or of Vorschütz's safety-pins fully controls hemorrhage from the scalp. Bleeding from the bone is likewise adequately arrested by means of wooden or bone pegs, plugs of cotton wool, and Horsley's wax. Hemorrhage from the dural vessels is stayed by means of gentle pressure with gauze, the application of a flattened bit of muscle to the bleeding point, underrunning the latter with a fine silk ligature, or the use of Cushing's silver wire clips. The troublesome bleeding from the superficial vessels of the brain is controlled by means of pressure with dry gauze or gauze wrung out in hot saline, or, if this fails, by the use of fine silk ligatures. All these are mentioned in order to show how the management of small details has greatly broadened the scope of cranial surgery.

It is impossible to enumerate in this place more than a few of the modern advances in this field of surgery. One of the most important of these is the recognition of the value of decompression in the relief of many cerebral conditions. Rawling prefers the musculotemporal decompression operation of Harvey Cushing to that of cerebellar decompression. He regards venesection as a valuable means of reducing the minor grades of increased intracranial pressure and finds that lumbar puncture is of little use in reducing the general intracranial pressure. Operative interference is invoked in the early stages of severe cerebral injuries, and in such remote effects of the latter as neurasthenia, cephalalgia, epilepsy, and insanity. In discussing the results of operations on brain tumors, Rawling states that with the improved technique of brain surgery and with more exact localization the mortality has diminished from 40 to 20 per cent., and that the great secret in operating lies in knowing when to give up the attempt at removal and when to be satisfied with a mere decompression operation.

It is curious to note that trephining is a branch of surgery that was widely practised even in prehistoric times. The neolithic skulls unearthed in France and the skulls of the pre-Columbian period discovered in Peru, bear ample evidence of the widespread use of this operation. The perfection with which square and round openings, small and large, single and multiple, were made by means of stone or flint implements, the site of election of these trephine holes upon the parietal region of the skull, at a safe distance from the venous sinuses—all indicate that the prehistoric surgeons had considerable knowledge of cranial anatomy and performed this operation with definite indications in view. Thirty-five years ago the distinguished French surgeon Lucas-Championnière published an exhaustive historical and clinical study of trephining, a work which first drew attention to the surgical possibilities of this operation. Today the same writer* returns to his early theme and shows that many of the older theories as to the purpose of the prehistoric trephining are erroneous. Broca was one of those who advanced the view that the primitive operation was performed on individuals in order, as the ancients thought, to permit of the escape of demons that were the cause of mental alienation or malefaction. The operation is performed at the present day among savage and semicivilized races, notably among the Kabyles of Algeria and the mountaineers of Montenegro, just as it was practised by the ancient Peruvians. Among the Kabyles the art is transmitted from father to son, and one instance is recorded in which the operation was performed on an individual, himself an expert operator, a dozen times. The purpose of the tribal surgeon is to relieve persistent headaches. He has no conception of the efficacy of this operation in the treatment of cranial fractures or other trau-

*"Les Origines de la trepanation décompressive, trépanation néolithique, trépanation pré-Colombienne, trépanation des Kabyles, trépanation traditionelle." Par le Dr. Lucas-Championnière, Membre de l'Institut (Académie des Sciences); Chirurgien Honoraire de l'Hôtel-Dieu; Membre de l'Académie de Médecine; Ancien Président de la Société Internationale de Chirurgie. Avec 32 figures. Prix 5 fr. Paris: G. Steinheil, 1912.

matisms. In fact, fractures of the skull among the Kabyles are practically unknown. None of the prehistoric trephined skulls shows any evidence of a fracture. Unless the entire fractured area was wholly removed in every instance, which is regarded as improbable, Lucas-Championnière concludes that the purpose of neolithic and pre-Columbian trephining was the same as that of semi-civilized races to-day, namely, the relief of headache. In other words, the primitive surgeon, with his sharpened flint, had practised cerebral decompression just as it is advocated in modern cranial surgery.

The Anti-alcohol Physicians in Munich.

The personnel and point of view of medical men who practise where the per capita consumption of alcoholics reaches a high point should be of interest to physicians of the United States. It is somewhat unfortunate that many of the latter, when they pronounce against alcohol speak simply as asylum physicians or proprietors of sanatoria for alcoholics and drug addicts and seem to be incapable of forming an unbiased judgment regarding the moderate use of alcohol by sane individuals. The men of Munich who are opposed to the use of alcohol appear to be those who are naturally concerned with children and youth and with those who, if intoxicated, are actually a direct menace to the common welfare. At the annual meeting of the German Medical Temperance Society (*Münchener medizinische Wochenschrift*, June 17, 1913), Engel said he had been endeavoring to convince chauffeurs and owners of automobiles of their peculiar dangers from alcohol. His leaflets were mostly accepted in the proper spirit, although one club refused them. Hecker, representing the school physicians, spoke of enlightening the growing child as to what alcohol may do to him, and we can well imagine that in a community where children receive beer at home, often from infancy, such instruction is bestowed to some purpose. Bayr showed by psychological tests the mental inferiority of school children who had become alcoholized. The percentage of child teetotalers is increasing, and all who have any supervision of youth, including athletic instructors, are asked to see that as far as possible children grow to manhood without alcohol. There is no suggestion here of antagonism toward adults who are not abstainers, and even dealers are not abused. The harm exerted by alcohol upon children seems to be a matter of proof, although the documents by Zieben, Kraepelin, and others based on the effects of alcohol on adults are not applicable to children who require proofs adapted to themselves alone. The psychological studies of Bayr already mentioned, upon children who have already become addicted to alcoholics, gives us the desired method, which has been corroborated over and over and in different countries.

Primary Tuberculosis of the Gums.

Benign or semibenign tuberculosis of the gums in a healthy subject is not of very common occurrence, and the description of a case given by Van Tappeiner at the Greifswalder Medizinischer Verein (*Deutsche medizinische Wochenschrift*) will serve to call the attention of doctors and dentists anew to the subject. The patient was a boy aged 16. For two years past he had suffered from a chronic affection of the upper gum, characterized by increased swelling and frequent hemorrhage and pain. That part of the gum actually involved was the anterior aspect of the alveolar processes of the upper jaw, and the tissues between the right and left canine teeth were relaxed, swollen, and hemorrhagic. This area was sharply marked off from the sound adjoining mucosa of the upper lip, and also projected considerably above it. Processes of the inflamed gum extended between the teeth, and even into the carious cavities. The mucosa of the gum in this area seemed to have vanished. All the regional lymph nodes were swollen. In treating this case all the inflamed gum was extirpated, and the Paquelin cautery applied to the raw surface. The tissues so removed showed to the microscope typical tuberculous nodules; also the fragments from curettage of the teeth cavities gave positive finds. Some teeth which had become loosened were made fast. The lymph nodes were treated with the *x*-rays.

News of the Week.

Safety Exposition.—The First International Exposition of Safety ever held in America will, as previously announced, be held in New York from December 11 to 20, 1913. The exposition will be unlimited in its scope, embracing everything devoted to safety, health, sanitation, accident prevention, and the advancement of the science of industry.

Treatment of Poliomyelitis.—The Hospital of the Rockefeller Institute for Medical Research announces that, beginning on July 15, cases of poliomyelitis will be received for treatment in the hospital during the summer, as during the two previous summers. Physicians desiring to secure hospital treatment for patients ill with this disease are invited to telephone to the Rockefeller Institute (Plaza 6800), when the hospital officials will arrange for the sending of an ambulance for the case.

Historical Medical Museum.—The ceremony of opening the Historical Medical Museum of London, organized by Mr. Henry S. Wellcome, was performed on June 24 by Dr. Norman Moore, in the presence of Sir Thomas Barlow, president of the Royal College of Physicians, Sir Frederick Treves, Sir Rickman Godlee, president of the Royal College of Surgeons, and Sir Francis Champneys, president of the Royal Society of Medicine. The museum contains a remarkable collection of rare and curious objects of historical interest connected with medicine, surgery, and the allied sciences from all parts of the world, and will be an important addition to the studies of the International Medical Congress. The present collection is to form the nucleus of a permanent Historical Medical Museum in London. This is distinct from the general medical museum referred to below.

Medical Congress Museum.—Arrangements for the organization of a museum in connection with the International Congress of Medicine to be held in London next month have been entrusted to a committee headed by Prof. A. Keith of the Royal College of Surgeons, London. Exhibits illustrative of subjects to be discussed in the different sections of the Congress will be contained in the Museum, and it is believed that such a central collection will have many advantages over the exhibits of former years, which have been arranged and exhibited by each section separately. Accommodation has been se-

cured at the Imperial College of Science, South Kensington, and the committee appeals for exhibits, which it will insure against damage and loss. It will also pay all costs of transit. Communications in regard to exhibits may be addressed to the Honorable Secretary of the Museum Committee, H. W. Armit, Ravenhurst, Talbot Road, Wembley. It is expected that the museum will be kept open for a few days after the Congress has ended.

The International Association of Medical Museums will hold its second triennial meeting at the Museum of the Royal College of Surgeons and at the Museum of the XVII International Medical Congress, London, on August 5-7, 1913. The address of the president, Dr. Aldred Scott Warthin of Ann Arbor, Mich., will be on "The Ideals and Functions of the International Association of Medical Museums." There will be a symposium on replies received to the "experience circular," giving various details of preferred methods of preparing and preserving specimens, and also a number of set papers and demonstrations on museum technique both macroscopic and microscopic.

Radium Supply.—It is reported that German agents have bought up all the available radium in England, which amounted to only one-eighth of the quantity desired, and that the price paid was at the rate of $2,400,000 an ounce, cash down.

Dole for Blind.—The blind poor of the Borough of Manhattan, New York City, received, their semi-annual allowance from the Department of Charities on July 18. The sum of $25 each was given to 555 blind persons, the requirements being that the person must be a citizen over twenty-one years of age, an inhabitant of the city for more than two years, and without near relatives competent to support him.

County Tuberculosis Hospitals.—The Boards of Supervisors of New York State have recently provided for the erection in their respective counties of hospitals for the treatment of tuberculosis. In Cattaraugus County the Board appropriated $18,000 to build such a hospital and appointed a committee to acquire a site. In Onondaga County plans calling for an expenditure of $154,000 for the building of a tuberculosis hospital were approved, and an appropriation of $37,000 additional for a site was made. In Schenectady County $10,000 was appropriated for a twenty-bed addition to the present County Tuberculosis Hospital. Finally, in Saratoga County the Board voted to increase its former appropriation of $8,000 to $30,000, and let contracts for the construction of the hospital.

Hospital Site Sold.—The Governors of St. George's Hospital, London, have accepted a proposal for the sale of their present site for $2,350,000, and will probably amalgamate with the Westminster Hospital in the erection of new buildings in a suburb of the city. It is reported that a large hotel will be erected on the hospital site which is directly opposite the Piccadilly entrance to Hyde Park and has long been regarded as one of the finest sites in London. The hospital by the term of the contract will remain in possession for two years longer, by which time the new buildings will be ready.

Dr. Burdette L. Arms, formerly director of the Boston Bacteriological Laboratory, has been appointed State Superintendent of Bacteriology of Oregon.

Dr. James F. Donnelly, formerly of this city, has removed to Highlands, N. C., where he is one of the physicians in charge of the Highlands Camp Sanatorium.

Professor Carl von Noorden has decided to resign his professorship in the University of Vienna and return to Frankfort. Professor His of Berlin is mentioned as his successor, but it is doubtful whether he would be willing to leave Berlin to go to Vienna.

Centenarian Dead.—Mrs. Freda Bidietzky of Philadelphia, said to be 109 years old and the oldest inhabitant of the city, was found dead in her bed on July 15.

Congress on School Hygiene.—Mayor Gaynor has appointed the following persons to represent the City of New York at the Fourth International Congress on School Hygiene in Buffalo next month: Dr. Luther H. Gulick, Dr. L. Pierce Clark, Miss Lillian D. Wald, Howard Bradstreet, Lawrence Veiller, Owen Lovejoy, Mgr. Lavelle, Dr. L. Emmett Holt, Miss Eleanor H. Johnson, Health Commissioner Lederle, and Frank H. Mann.

State Statistics.—For the month of May, 1913, statistics show that 12,261 deaths occurred in New York State, and that for the same period the births numbered 18,260. The number of deaths was 250 greater than that for the same month of 1912. Pulmonary tuberculosis caused 1,309 deaths, other forms of tuberculosis, 216; cancer, 699; Bright's disease, 885; pneumonia, 826. There were 128 suicides; 117 persons were drowned; 43 murdered, and 5 killed by electricity. Old age was the cause of death in 155 cases, and railroad accidents were responsible in 125.

Infant Mortality Low.—During the week ending July 12, there occurred in New York City 272 deaths of infants under one year of age, as against 309 in the corresponding week of 1912.

Bequests to Charities.—The German Hospital of Philadelphia receives a bequest of $1,000 under the will of the late Otto Bacmeister of Philadelphia, and a bequest amounting to one-ninth of the estate of Barbara Tresch, who died recently in Switzerland.

By the will of the late Isaac Blum of Philadelphia the sum of $250 each is bequeathed to the Jewish Hospital and the Mount Sinai Hospital, the sum of $200 to the Philadelphia Jewish Sanitarium for Consumptives and the sum of $150 to the Jewish Maternity Hospital.

Reciprocity in Oklahoma.—The State Medical License Board of Oklahoma now reciprocates with New Mexico, Texas, Nebraska, Nevada, South Dakota, Michigan, Wisconsin, Arkansas, Mississippi, Kentucky, Tennessee, North Carolina, and West Virginia.

California Medical Practice Law.—A new Medical Practice Act for the State of California becomes effective August 11, 1913. It makes provisions for the indorsement of the licenses of applicants from other states if their qualifications prove acceptable. It also provides for the granting of a license without examination to applicants who have served in the regular U. S. Army or Navy Medical Corps. The new Secretary of the Board is Dr. Charles B. Pinkham, 929 Butler Building, San Francisco.

Medical Society Elections.—AMERICAN INSTITUTE OF HOMEOPATHY.—At the sixty-ninth annual convention of the American Institute of Homeopathy, held last week in Denver, the following officers were elected: *President,* Dr. Dewitt G. Wilcox of Boston; *First Vice-President,* Dr. Grant S. Peck of Denver; *Second Vice-President,* Dr. Anna B. Varner of Pittsburg; *Treasurer,* Dr. Thomas Franklin Smith of New York; *Secretary,* Dr. J. Richey Horner of Cleveland.

Maine Medical Society.—At the conclusion of the annual meeting held in Portland on July 3, the following officers were elected: *President,* Dr. William C. Peters, Bangor; *Vice-Presidents,* Dr. Eben J. Marston, Bath, and Dr. Caleb J. Emery, Biddeford; *Secretary,* Dr. John B. Thompson, Bangor; *Treasurer,* Dr. E. W. Gehring, Portland.

Dallas Medical and Surgical Society.—The following officers were elected at a meeting held in Dallas, Tex., on June 28; *President,* Dr. John M. Neel; *Vice-Presidents,* Dr. S. E. Milliken and Dr. R. B. McBride; *Secretary,* Dr. F. A. Pierce; *Treasurer,* Dr. A. M. Gantt.

Iowa and Illinois Central District Medical Association.—At the annual meeting of this society, held in Davenport, Ia., on July 10, the following officers were elected: *President,* Dr. Peter A. Bendixen, Davenport; *Vice-President,* Dr. Frank H. Gardner, Moline, Ill.; *Secretary,* Dr. Lawrence W. Littig, Davenport; *Treasurer,* Dr. F. H. First, Rock Island, Ill.

Lehigh Valley (Pa.) Medical Society.—At the annual meeting held at Buckwood Inn, Shawnee on the Delaware, on July 17, the following officers were elected for the ensuing year: *President,* G. S. Seiberling, Allentown; Vice-Presidents, J. G. Sern, Lehighton; J. E. Williams, Wilkesbarre; H. D. Keller, Bangor; J. H. Sterns, Delaware Water Gap; *Treasurer,* A. A. Seem, Bangor; *Secretary,* J. W. Luther, Palmerton. *Executive Committee,* F. B. Lydle, Birdsboro; J. N. Richards, Falsington; J. N. Best, Rosemond; J. B. Corser, Scranton; I. R. Bucher, Lebanon; J. Hornbeck, Catasauqua; U. E. Beckman, Wilkesbarre; E. H. Kistler, Lansford; W. L. Angle, East Stroudsburg; J. G. Mensch, Pennsburg; A. L. Kotz, Easton; Mary Dekay, Sunbury; David Taggart, Frackville; C. M. Williams, Washington, N. J.

Obituary Notes.—Dr. George W. Terriberry of Paterson, N. J., a graduate of the Bellevue Hospital Medical College, New York, in 1886, a member of the New Jersey State and Passaic County Medical Societies, a veteran of the Civil War, and formerly surgeon-general in the New Jersey National Guard, died at his home from heart disease, suddenly, on July 14, aged 73 years.

Dr. Charles Plummer Morrill of North Andover, Mass., a graduate of the Georgetown University School of Medicine, Washington, in 1866, a veteran of the Civil War, and a member of the Massachusetts State and Essex County Medical Societies, died at his home on June 27, aged 73 years.

Dr. William Henry McFadden died at Philadelphia on July 2 at the age of 85 years. He was graduated from the college department of the University of Pennsylvania in the class of 1849 and from the medical department of Pennsylvania College at Gettysburg in 1852. In 1873 he became chief engineer in the Philadelphia Water Bureau and he continued in this position until 1883. Later he was connected with the Camden Gas Works and the American Gas Meter Company.

Dr. Ferdinand N. Sauer of Jersey City, N. J., a graduate of the College of Physicians and Surgeons of Baltimore in 1901, a member of the American Medical Association and the New Jersey State and Hudson County Medical Societies, and formerly chief inspector of the Jersey City Board of Health and credited with the organization of pasteurized milk depots and clinics for the poor of the city, died at his home on July 8, aged 39 years.

Dr. Ruth A. French of San Diego, Cal., a graduate of the Woman's Medical College of Pennsylvania in 1867 and at one time professor of anatomy in that institution, died at her home on June 23, aged 74 years.

Dr. David Howland Cannon of Mattapoisett, Mass., a graduate of the Harvard Medical School, Boston, in 1873, and for many years chairman of the Mattapoisett Board of Health, died at his home on July 2, aged 69 years.

Dr. Soloman A. Metty of Topeka, Kan., died at his home in that city on June 30, aged 77 years.

Dr. William Joseph Glinnen of Brooklyn, a graduate of the Bellevue Hospital Medical College, New York, in 1897, died in St. Catherine's Hospital, Brooklyn, following an operation for appendicitis, on July 13.

Dr. Warren Nichols Horton of Los Angeles, Cal., a graduate of Washington University Medical Department, St. Louis, in 1903, professor of genitourinary diseases in the College of Physicians and Surgeons of Los Angeles, formerly city bacteriologist, and a member of the American Medical Association and the California State and Los Angeles County Medical Societies, died suddenly at the Angelus Hospital after an operation for appendicitis on July 5, aged 32 years.

Dr. Clinton H. Catherwood of Denver, Col., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1895, died at his home from tuberculosis on July 1, aged 40 years.

Dr. Jethro G. Bohannon of Greenville, Ky., a graduate of the University of Louisville, Medical Department, in 1874, a member of the Kentucky State and Muhlenberg County Medical Societies, and for many years a member of the Muhlenberg County Board of Health, died at his home on July 4, aged 62 years.

Dr. Wallace B. Deffenbaugh of St. Joseph, Mo., a graduate of the Starling Medical College, Columbus, O., in 1885, professor of obstetrics in the Ensworth Medical College of St. Joseph, and a member of the American Medical Association, the Missouri State and Buchanan County Medical Societies, and the St. Joseph Surgical Society, died suddenly in his office on July 2, aged 52 years.

Dr. Charles O. McCune of Unionville Center, O., a graduate of the College of Physicians and Surgeons of Baltimore in 1879, and a member of the Ohio State and Union County Medical Societies, died at his home suddenly on July 5, aged 66 years.

Dr. William Wayne Ashhurst of Philadelphia, a graduate of the Medical Department of the University of Pennsylvania, and for sixteen years a practitioner of Chihuahua, Mexico, died at University, Va., after a long illness, on July 14.

Dr. Isidore Clarence Smulyan of Salt Lake City, Utah, a graduate of the Baltimore Medical College in 1901, died at his home from pneumonia on June 30, aged 35 years.

Dr. Clark Ingersoll Wertenbaker of Washington, D. C., a graduate of the Georgetown University School of Medicine, Washington, in 1894, a member of the American Medical Association, formerly first lieutenant in the Medical Reserve Corps of the United States Army, died at his home on July 6, aged 39 years.

Dr. Leland H. Munger, of Winona, Minn., a graduate of the Missouri Medical College, St. Louis, in 1879, and a member of the American Medical Association and the Minnesota State and Winona County Medical Societies, died at his home on July 9, aged 56 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

HOSPITALS ASSOCIATION—FEEDING SCHOOL CHILDREN—ST. JOHN'S HOSPITAL—PARLIAMENTARY RETURN ON INSURANCE ACT—BIRTHS AND DEATHS FOR 1912—DR. GOULD GIVES RADIUM TO HIS HOSPITAL—SIR CH. TUPPER—HUNTERIAN MUSEUM—R. C. S. ELECTION—OBITUARY.

London, July 4, 1913.

On the concluding day of the annual conference of the Hospitals Association, Sir William Osler again presiding, Mr. Keith Young read a paper on the cost of maintenance which he showed was affected by mistakes in planning as well as errors of construction, including the use of inappropriate material. As an example, he said excessive length of corridors increased the cost of cleaning, whitewashing, and heating. Mr. Conrad Thies urged the importance of taking the best advice of engineering, electrical and building experts in addition to that of the architect. In a visit to a very large hospital in course of erection he was astonished to find a number of points likely to cause trouble in a few years. At St. Bartholomew's in a receiving room almost perfectly equipped there was no provision for wheeling patients into the casualty room instead of carrying them up steps. It seemed almost incredible. Sir Henry Burdett considered the plan of Bartholomew's was wrong. They could not find an architect to carry out a modern hospital without such mistakes. An expert hospital administrator ought to be associated with the architect. He deprecated interference with plans after they had been accepted and lamented that medical men did not realize the waste of money that was caused by failure to think out their requirements before the plans were made. Sir William Osler, returning thanks for re-election as president, said they looked to those who managed the hospitals to carry out the new ideas that were continually coming forward. He referred to the Peter Brigham hospital at Boston as the realization of a new ideal. There they had built only two units—the medical and surgical—and what impressed him was the simplicity. In future the profession would ask for hospitals to be built on lines not yet realized—on lines of individual units, each to be in charge of a single person, with groups of assistants and with laboratories and equipments ready to hand. This generation might not be asked to do it, but he had no doubt that doctors and workers would in the future demand hospitals so constructed.

The teaching of school children has been the leading subject discussed at a conference held this week at the Guildhall, the Lord Mayor looking in from time to time to welcome the members of the various institutions taking part. Overcrowding bulked largely in the view of teachers, who further complained that the classes were as a rule too large for the best results to be attained. Malnutrition, anemia, and various debilitating diseases, even tuberculosis, were dealt with by an assistant school doctor as prevalent in slum districts, where the children were not sufficiently in the open air. Another advocated the natural remedy, open air meals, open air employments and exercise as parts of the curriculum. The "Free Meal Act" was generally held to have been successful, and the manner of carrying it out by different local authorities freely discussed. Many congratulated themselves that this is the age in which the children, after generations of neglect, seem to be coming into their rights. On the other hand, one hears outside these educational assemblies an undercurrent of doubt as to how far this socialistic dependence on the State is to carry us. Free education, free doctoring, free meals and so on, they say, it will soon be everything free and the boasted British independent spirit gone. But as to the working of the free meals by local authorities, the plan adopted by Bradford was described by the superintendent as giving varied palatable meals under the management of persons in sympathy with children, so as to secure order, brightness and good manners. In that city breakfasts and dinners were prepared in a central kitchen and taken in cans and boxes by motor van and tram car to the several dining rooms where teachers and monitresses who volunteered for the work served the food. To determine who were entitled to partake, the rule was that when the total weekly income of the family, after deducting rents, was less than 3s. per head dinner was allowed; when less than 2s. per head, breakfast also. The result was declared to have been evident in the increased physical strength, mental alertness and better manners of the children thus treated. Other plans were described, and it was urged that the intimate association of the work with the medical service department showed that it should be supervised by the doctor, who should examine each child at definite intervals and remedy any physical defects. The teeth should specially be watched and attended to, which seems to prepare for the demand of dental surgeons being appointed. Sir George Kekewich, presiding at one of the meetings, said free meals formed the corollary of free education without being socialistic. Dr. Bulger admitted this but added that the result of philanthropic efforts had too often been to cultivate the "rotter."

The history of St. John's Hospital for Diseases of the Skin is a story of successive disputes which concern the medical staff. Those old enough to remember its being started trace back disagreements almost to the beginning. The constitution of the hospital is very unusual, perhaps unprecedented, for it has been registered as a corporation and its rules must be in accordance with the law of such bodies and embodied in articles of association. The committee are the governing body and can perform all acts which consist in conducting the institution within the legal limits applicable. The last dispute has brought them into the law courts. It seems to have arisen in the old familiar story of friction in the medical staff, and very disagreeable allegations were bandied about and reached the public ear and some were repeated in the trial and not refuted. Certain representations were made to the committee by the majority of the staff—practically all except the senior, who was a member of the committee and opposed his colleagues. The dispute grew and eventuated in the committee dismissing the opposing members of the staff from their posts. Three of these, with the support of others, appealed to the Court (King's Bench) as to whether the committee possessed legal power to summarily get rid of them and asking to be reinstated or otherwise awarded damages. Here comes in the point of the constitution, for they were all members of the corporation which owned the property of the hospital, and it was asserted that the directors of a company could not exclude shareholders, even if they could servants. The judge held that the articles and rules

did not justify dismissal and ruled that the plaintiffs remained members of the corporation, awarding them damages of £50 each with costs, but he declined to grant an injunction to restrain the committee from excluding plaintiffs from the hospital.

A parliamentary return shows that to April 30 last 24,533 applications for sanitarium benefit under the Insurance Act were received. Of these, 2,183 were ineligible, 20,414 were recommended and 19,097 received the benefit. In residential institutions 10,239 were under treatment, 2,797 receiving dispensary and 6,661 domiciliary treatment. The cost was stated as £171,888.

From a summary of the Registrar-General's statistics for 1912 the birth rate and death rate both show the lowest figures on record. The death rate represented 13.3 per 1,000. The infantile mortality also was the lowest recorded—95 out of each 1,000 children born dying before the end of their first year.

Sir A. Pearce Gould has given £1,000 to the Middlesex Hospital to buy radium, requesting it may be used for the treatment of patients, especially those with malignant disease.

Sir Charles Tupper, whose remarkable career in politics will be known to you, is a medical graduate of Edinburgh, probably the oldest living, as he kept his 91st birthday on Wednesday. He has crossed the Atlantic 64 times, has been in Canadian politics since 1855, retiring in 1900.

The additions to the Hunterian Museum for the past year were on view yesterday and will remain for three weeks. There are 830, many of them most interesting.

Yesterday was the election of four Fellows to fill vacancies at the Royal College of Surgeons. The poll resulted in the election of Messrs. Ernest Lane, H. J. Waring, L. A. Dunn, and J. Hutchinson.

Surgeon Lieutenant-Colonel Horace Par Yeld, late of the Indian Medical Service, died at Harrogate on June 21, in his sixty-sixth year. He was in the Afghan War, for which he held the medal. Later he became deputy assay master of the Calcutta and Bombay Mints, and retired in 1894.

Brigadier-Surgeon E. Sexton died on June 25. He graduated at St. Andrew's in 1856 and at once entered the Naval Medical Service. Two years later he left this and joined the Indian service and was engaged in the military works until he retired in 1889.

Mr. Alfred Willett, Consulting Surgeon to St. Bartholomew's Hospital, died on June 30, aged seventy-six years. He was held in the highest esteem by the profession generally throughout his career. He qualified in 1859, took F.R.C.S. in 1862, was elected on the Council in 1887, and became vice-president and held other offices, including examiner in Cambridge University and the London Royal College of Physicians. He took a great interest also in King Edward's Hospital Fund. He was not a frequent contributor to the press, though he attended the societies and sometimes spoke, but his great work was as a clinical surgeon and teacher. He gave the Bradshaw lecture in 1897, taking for his subject "The Operative Treatment of Deformities."

Dr. Roderick Maclaren, consulting surgeon of the Carlisle Infirmary, who died on June 17, was one of the most distinguished provincial surgeons. He took the Edinburgh Medical in 1865, and after a voyage for health settled in Carlisle. He was elected surgeon to the infirmary in 1874 and remained until 1903, when on retirement he was made consultant. His eldest son succeeded him at the Infirmary.

OUR CANADIAN LETTER.

(From our Regular Correspondent.)

MEETING OF THE CANADIAN MEDICAL ASSOCIATION

The proceedings of the public health section were possibly of the most interest as well as the most important of any of the meeting. The first paper read was the report of the committee on medical inspection of schools by Dr. John Stewart of Halifax. Dr. Stewart's paper was read by proxy, he being in Edinburgh whither he had gone to receive the degree of LL.D. from Edinburgh University, his alma mater. Dr. Stewart after reviewing the work being done in all the provinces stated that he was compelled to conclude that medical inspection of schools in Canada was yet in its elementary stage. While progress had been made in the cities, owing to the efforts of the few, apathy was still exhibited in the smaller places and this condition of affairs would continue to exist until some definite system had been worked out that would constitute a national standard. For this reason, therefore, there was need for a national public health service that could deal with such questions as immigration, sanitation of factories, control of diseases, adulteration of food along with medical inspection of schools.

A lengthy discussion of the question took place and a committee was appointed consisting of Dr. James Halpenny of Winnipeg, Dr. Park of Edmonton, and Dr. J. Hutchinson of Westmount. The chief recommendation of this report was that for the present the inspection of children should be done by an appointee of the school board working in conjunction with the medical officer of health. At the close of a long discussion on this recommendation, it was decided to leave the matter over for another year and to have it take a prominent place on the programme of the next convention. A considerable difference of opinion existed as to which body should control the inspection of children, the school authorities or the board of health.

Another very important matter discussed was that of the control of venereal diseases. Two papers were read dealing with the question—one by Dr. H. W. Hill of London and the other by Dr. F. A. Clarkson, Toronto. Dr. Hill said in part that in many respects syphilis might be compared with typhoid fever and as it was criminal for a city to allow its citizens to drink polluted water, in his opinion so should it be criminal to allow venereal diseases to spread, destroying the race and blasting future generations. While in one respect it was a question of morals, it was likewise a physical matter involving the future well being of the race and as such should receive the legislative attention its importance entitled it to. During the discussion Dr. Adami of Montreal advised that the moral aspects of the case should not be considered. Not because the profession was not heartily in accord with the views of the moralists, but because the view of the medical profession was purely a physical one.

Dr. F. A. Clarkson in his paper advocated the establishment of segregated areas with medical inspection as a means of preventing the spread of venereal diseases.

Dr. Dill in the discussion that followed pointed out that moral suasion had been tried for centuries

without any good results and said that it was now necessary that legislation be introduced which would control the spread of such diseases. Dr. Hutchinson of Westmount thought that what moral suasion could not accomplish, legislation would not. Dr. R. E. Woodehouse of Port Arthur said that in Fort William there was a segregated area and that this plan tended to keep down the spread of venereal diseases. Dr. Halpenny of Winnipeg totally disagreed with the view that segregated areas had any influence on the spread of these infections, and held that where there was a segregated area disease was spread among shop and factory girls. Prostitutes, as a rule, were careful to avoid diseases, since their living depended upon their health. He declared that in his opinion segregation always was and must always be a hopeless failure. He suggested that hospitals and jails be required to report on all cases of venereal diseases coming under their notice. Dr. Adami of Montreal pointed out that in some countries no statistics as to prevalence of venereal diseases were available and in few countries were figures relating to this matter sufficent to be of much use. Sweden had been the first country to demand notification of syphilis and gonorrhea and in parts of Australia efforts in this direction had been put forth. The first step to be taken was to procure statistics with regard to the prevalence of venereal diseases and the aid of legislatures should be invoked for this purpose. A committee to report on the subject was formed composed of the following members: Professor Harris of Halifax; Dr. Bapty of Victoria, B. C.; Dr. Halpenny of Winnipeg, Dr. Hill of London, and Dr. E. L. Williams of London. In this report the recommendation was made that Provincial Boards of Health be asked to have venereal diseases added to the list of reportable infectious diseases.

Dr. George Nasmith of Toronto read a paper on milk supplies, pointing out the need for absolute cleanliness from start to finish. There should be regular inspection by municipalities and in addition farmers should be encouraged to use the "cow test" to insure quality. The only way of making milk an entirely safe article of diet in its uncooked state was by pasteurization. Dr. Bryce of Ottawa threw out the suggestion that municipal control of milk supplies would be a good thing. The control of supply and delivery of milk was in municipal hands in Wellington, N. Z., and the system was working well.

Dr. Lewellys F. Barker of Johns Hopkins University, Baltimore, gave an address on "Mental Hygiene." He said in part that by this term was meant the conservation and improvement of mental health to make men think better, act better, and become better than now. The imbecile, the criminal, the prostitute, the insane, were so because they had to be. Their minds worked that way. The majority had been born with a bad brain and acted as their brain directed, while others, though born with a good brain, because of some deleterious act, acted wrongly or criminally. Two sciences were dealing with the problem of mind improvement. One was the science of eugenics and the other was that of euthenics. The advocates of the first believed largely in heredity and were endeavoring to bring children into the world equipped with good brains. The other school believed that environment played the larger part in the development and expression of brain power. Both schools were of equal importance and there should be no quarrel between them. Dr. Barker sketched the recent campaign in the United States to make the public, the medical men, and the law givers recognize the importance of the question of mental hygiene. Criminality, prostitution, imbecility, and the like were due to bad brains, and by enacting proper laws to prevent marriage of the unfit, to check the spread of diseases that affect the physical well being of the coming generation, much of the evil could be stamped out. The benefit of institutional training for the mentally unfit was highly extolled by Dr. Barker. He said that in his opinion psychiatric clinics should be held frequently, and that school teachers should be educated to recognize the abnormal children and segregate them or have them placed in institutions where their mental well being would be assured. Such a campaign according to Dr. Barker ought to produce as good results in Canada as it had in the United States.

Dr. Hill of the Institute of Public Health, London, gave an account of health statistics secured from the parents of 8,000 children attending the schools of London. He computed that each child in the city had 2.5 infections during the ages from 5 to 12. Taking the figures as typical of the whole province he concluded that during each year there were 300,000 cases of infectious diseases, which at the very low estimate of $2 per case would mean that the province expended $600,000 annually for the care of these cases. The monetary loss was great, not to mention the deaths and suffering following. Medical men should do all in their power to prevent the spread of these preventable diseases Every year there were at least 15,000 cases of scarlet fever in Ontario, 37,500 cases of measles, and 27,000 cases of whooping cough.

Dr. Helen MacMurchy of Toronto presided excellently well over the public health section and on the evening of June 26 delivered an illustrated lecture on public health. Dr. MacMurchy made the statement that the standard of public health was high in Canada.

1. The Typhoid Carrier Problem. C. L. Overlander.
2. The Treatment of Cardiac Edema with Alkali and Salt. L. H. Newburgh.
3. Cancer of the Stomach. P. E. Truesdale.
4. Some Relationships between Orthopedic Surgery and Internal Medicine. H. W. Marshall.
5. Report of Eighteen Cases of Separation of the Lower Femoral Epiphysis at the Boston City Hospital. H. Binney and F. B. Lund.
6. Excessive Polyuria of Arteriosclerosis. W. E. Paul.

1. **The Typhoid Carrier Problem.**—C. L. Overlander believes that until some more easy, rapid and accurate method has been devised for determining the presence of the typhoid bacillus, and until one can effectively rid persons of this microorganism, detention of such persons in quarantine until successive negative findings, of exceedingly doubtful value, have been obtained, is an unwarranted proceeding, viewed from the standpoint of either the patient himself, the health officer, or the community. Such a procedure, involving a false confidence in their freedom from infected material, in those released, would be productive of more harm than good. It would be more practical and less arduous and would better conserve the public health to regard each person recovering from typhoid fever as a potential carrier, to carefully instruct him concerning this subject and

the precautions he should take, and if possible to forbid him to personally handle public food supplies. The application of any approved method, however good it may be, must not be limited to any community, city, state, or nation. It is a problem world-wide in its scope.

2. Treatment of Cardiac Edema with Alkali and Salt.—L. H. Newburgh has found that the administration of alkali in cases of cardiac edema does not cause diuresis. The administration of alkali plus salt in cases of cardiac edama does not cause diuresis. The administration of alkali plus salt to persons with heart disease may cause edema, and appears to be positively harmful.

5. Separation of Lower Femoral Epiphysis.—H. Binney and F. B. Lund state that owing to the danger of subsequent interference with growth, absolute reduction and fixation at the earliest possible moment are of great importance. Early and repeated *x*-ray examinations are necessary to control the completeness and permanency of the reduction. In simple cases, where immobilization in flexion fails to hold the fragment in correct position from the start, open reduction with the use of a small nail or bone-plate is indicated. In compound separation the same means of positive fixation is to be recommended. The foreign body should be removed soon after union has begun in order to avoid interference with growth. This should be done not later than the third week.

9. Interpretation of Pain in Surgical Emergencies. L. K. P. Farrar.

3. Industry and Disease of the Heart and Lungs.—J. M. Swan suggests that corporations interested in the health of their employees should require a certificate of health, based on a careful physical examination, from each individual on the payroll. Then the subsequent medical history of the employees might be studied and the occurrence of diseases among them could be recorded and investigated as to their relation to the work and to the habits of the employees when not working. In such a system, patients with heart or lung disease can be given suitable employment, and would not be set to work at tasks too great for them, as is now very frequently the case. Such an inquiry would be productive of much valuable information concerning the effect of industry on the health of the workers. It would require, however, for the best results, that the physician in charge of such a department should be a man of sound judgment, capable of undertaking original investigation.

9. Interpretation of Pain in Surgical Emergencies.—L. K. P. Farrar seeks to show that the inflammatory process going on in acute surgical diseases is accompanied by characteristic pain—that pain definite in character has a definite cause. Nature does not permit any severe injury to the body tissues without sending a message of protest. By the recognition of the pain the surgeon is frequently able to locate the organ affected, to judge of the degree of injury, and to give a prognosis of the result, whether he can detect the inflammatory process in the organ affected or not. The hernia that one can see enlarge and redden as it becomes obstructed is no more dangerous to life than the ulcer eating its way through the wall of the appendix to pour its infection into the unprotected abdomen, or the ectopic gestation opening up bloodvessels preparatory to a fatal internal hemorrhage, but it is much easier to convince a patient of the urgent need of an operation in an obstructed hernia than in an acute appendicitis or ectopic gestation. Unlike the experience of one's childhood, when the things one sees are not half as fearful as the things hidden in the dark, pain plus the sight of a tumor undoubtedly gains the patient's assent to operation far oftener than pain hidden in the abdominal cavity, even though that pain may be of a much more severe type.

1. Perforative Ulcer of the Stomach and Duodenum.—By J. B. Deaver. (See MEDICAL RECORD, July 5, 1913, Page 36).

3. Skin Complications of Diabetes.—B. Foster states that many general practitioners fail to appreciate the close relationship of the skin complications to diabetes of which they may often be the first symptoms. Among these he enumerates dryness of skin and pruritus, boils, carbuncles and mal perforans which last occurs in about 3 per cent. of cases. These are the commonest disorders. Psoriasis has been reported, but the author considers this only a coincidence. The early recognition of the cutaneous complication is important since, while the ultimate prognosis is probably bad, there are few other serious diseases which are more amenable to intelligent treatment, as regards duration of life and the comfort of the patient.

4. Transmission of Treponema Pallidum from the Brains of Paretics to Rabbits.—H. Noguchi has succeeded in producing syphilitic scleroses containing *Treponema pallida* in the testes of two rabbits by the inoculation of an emulsion of the brain obtained from a paretic individual. The lesions developed slowly, requiring in the one instance ninety-two and in the other one hundred and five days. Taken all together the percentage of successful inoculations is thus far small, since they were obtained with one brain out of six. Both in respect to the slow development of the lesions and to the low percentage of infections the result is striking when contrasted with what occurs on inoculation of chancres, condylomata, or secondary syphilitic papules. By using several rabbits the author has usually succeeded with every specimen of the latter, while he has been successful with only one specimen of brain out of six employed. The disparity is probably connected with the small number of *pallida* present in

the brain tissue, although it may be due to a low degree of infectiousness of the brain spirochetes for the rabbit.

10. **Mesenteric Cysts.**—C. H. Frazier reports a case of sanguineous cyst of the mesentery of the small intestine. The cyst and adherent loop of bowel were excised and the severed ends of the small intestine were united with the Murphy button. These cysts are usually oval in shape, though sometimes spherical as in the case described, and are generally found not far from the ileocecal valve, though occasionally elsewhere. Most of them are freely movable. Their growth is rapid and may be accelerated by accidents causing hemorrhages in the cyst. Percussion reveals a dull sound and an area of resonance around the mass and the cysts can usually be revealed by palpation. Other symptoms may be lacking, but usually the cysts manifest their presence by digestive disturbances and pain, simulating that due to intestinal obstruction. If intervention is delayed the patient may die of inanition. Radical removal is the best treatment when feasible, but when symptoms are acute incision and drainage is simpler and more liable to relieve, as it is more quickly done. Aspiration is obsolete. The cysts are of varied origin, and include hydatids and dermoids as well as sanguineous and lymphatic cysts and other varieties.

13. **Action of Emmenagogue Oils.**—D. I. Macht concludes that these are not innocuous and have absolutely no direct stimulating action on the uterine contractions or tonicity. On the contrary, they inhibit such contractions and even paralyze the uterus. Their action as abortifacients, if they act as such, is no different from that of any other powerful systemic poison, such as phosphorus or arsenic. They have very little if any therapeutic value, and do not deserve the place among the official pharmacological preparations which many of them hold.

14. **The Quinine Treatment of Pneumonia.**—S. Solis Cohen employs in this treatment the double chloride of quinine and urea introduced intramuscularly in a fifty per cent. solution; the hypodermic injection of cocaine hydrochloride solution or of an extract of the posterior lobe of the pituitary body for the maintenance of blood pressure; and in cases of prolonged fever, delayed resolution or tardy convalescence, the injection of bacterins. The initial dose of the guinine salt is from fifteen to twenty-five grains followed by fifteen grains every third hour until the temperature falls and stays down below 102.2° F. One-half grain of cocaine hydrochloride or of caffeine sodiosalicylate, or 1 c.c. of pituitary liquid, or 1 c.c. of the 1:1000 solution of the posterior pituitary principle is given with the first quinine dose and repeated likewise every third hour until the systolic blood-pressure curve in millimeters of mercury taken in the arm rises and remains above the curve representing pulse frequency in beats per minute. No invariable maximum limit has been fixed to the number of injections of quinine or pressor substances, but it has been considered best to continue them not beyond the first twenty-four hours and rarely as long as this. Where the desired effects have not been reached by that time, the interval between injections has been increased to six hours. In general the idea is to give as much quinine as can be borne in the first forty-eight hours and as little of the pressor drugs as is needed to maintain the systolic blood pressure a safe distance from the pulse rate. These directions apply to moderately strong adults with good results. Until recently this treatment was reserved for cases calling for active intervention and other patients were permitted to go without it. Statistics are based, therefore, on cases from the moderately severe to those of the very worst type. At present the author gives the first dose of quinine to every patient and the result has been that the cases have become so much milder that they require no further treatment beyond good nursing. As regards the duration of this treatment, the quinine is seldom continued beyond seventy-two hours and the number of injections ranges from one to fifteen and is ordinarily five or six, usually of about one gram each. The number of cocaine and pituitary injections ranges from one to twenty and will average three and four in each case, and each case must be judged by itself. The only general rule is to give enough to produce the desired effect and no more.

4. On the Possibilty of Achieving by Partial Pneumothorax the Advantages of Complete Pneumothorax in the Treatment of Pulmonary Tuberculosis. W. Parry Morgan.
5. The Difficulties of Tonsillectomy and How to Deal with Them. J. F. O'Malley.

1. **Surgery of the Large Intestine.**—Sir Berkeley Moynihan points out the surgery of the large intestine is chiefly concerned with three diseases—cancer, tuberculous tumors, and those simple inflammatory disorders which are grouped under the not very accurate or appropriate title, "diverticulitis." The merely technical aspects of this interesting subject have undergone notable improvements. Tumors of the large bowel can now be removed more widely, with greater safety, and with a higher degree of permanent success than would have been thought possible a few years ago. It is rare for patients suffering from a growth in the large intestine to complain of pain; there is more usually a sense of discomfort, of turmoil, of erratic and uneasy movements, with griping, accompanied by the noise of gas and fluid rolling about within the bowel. The borborygmi in the late cases may be very loud, so that they may easily be heard many feet away from the patient. It is a remarkable feature in cases of carcinoma of the colon that the patient is often able to localize the seat of the obstruction. He will describe the accumulation of flatus at a certain point in the intestine where the difficulty seems to lie, and may say also that a trickle of escaping fluid and gas is felt to be followed at once by relief. Alterations of the feces are usual in all cases. Blood is often present. In cases of carcinomatous growths in the ascending colon, and more rarely when the growth invades the cecum or the first part of the transverse colon, the presence of anemia may be observed. The anemia is stealthy in onset, steady in progression, and may often be very pronounced before any other symptoms have attracted attention. *X*-ray examination is a valuable aid to diagnosis. Of the conditions which imitate malignant disease very closely the most interesting is that now known as diverticulitis ("sacculitis" would be a better term).

2. **The Kinetic Theory of Shock.**—G. W. Crile presents a summary of a large clinical experience and of more than 1200 experiments on animals, most of the data of which have been published in detail in five monographs. He shows that shock may be produced by physical trauma with or without inhalation of anesthesia; that those parts of the body having the greatest number of nociceptors and which defend the most important regions by muscular action are the most shock-producing on receiving trauma. In the distribution of the defending nociceptors one perceives a brief epitome of the phyligenetic struggle for existence. Nitrous oxide anesthesia as compared with ether anesthesia is a protective agent against shock—protective through its interference with the use of oxygen by the brain cells—on the same principle as the action of a chemical fire extinguisher. The physical exhaustion and the brain cell changes are due to an adaptive response of the brain to the injury—a silent motionless effort to escape from the physical injury of the operation; if the field of

operation is blocked with local anesthesia, or if the nerve connection between the brain and the injury is blocked, physical injury can cause no shock. The motor mechanism may be powerfully driven by psychic stimuli—perhaps as powerfully as by traumatic and physical exhaustion—and corresponding brain cell changes are produced. If both the traumatic and the psychic stimuli are excluded shock cannot be produced. These physical changes in the brain cells are not produced by alteration in the gases in the blood or by metabolic processes from the shock-producing psychic or traumatic stimuli. The brain cell changes are not due to anemia from lowered blood pressure alone. One is forced to conclude that shock is an exhaustion phenomenon due to the driving of the motor mechanism by adequate stimuli, and that it is expressed by physical exhaustion and brain cell changes.

5. Accidents of Tonsillectomy.—J. F. O'Malley states that certain types of tonsil present difficulties to complete removal, and certain injuries to the soft parts are liable to occur until the operator has fully mastered the technique. These types and injuries are as follows: (1) The left tonsil in all cases; (2) the very large tonsil; (3) the "immobile" tonsil; (4) the small, flat, friable tonsil; (5) the "pulpy" tonsil; (6) removal of the uvula; (7) buttonholing the soft palate; (8) removal of portions of the anterior pillar (palato-glossus muscle), either its margin along the center or its lower end where it is inserted into the side of the tongue; (9) tearing the posterior pillar; (10) removal of portion of the pharyngeal aponeurosis; (11) tearing the mucous membrane over the point where the soft palate lies in relation to the hamular process of the internal pterygoid plate; and (12) hemorrhage. The author discusses the methods of avoiding the difficulties and dealing with the injuries.

5. On Psychoanalysis. D. Forsyth.
6. Observations on the Toxemias of Pregnancy, and on Eugenics from the Obstetric Standpoint. A. Routh.

1. Fatal Pellagra in Two English Boys.—C. R. Box describes two cases of pellagra that occurred in boys of the same family that had never been out of England. One of these boys, aged eleven, was admitted nearly three years ago to St. Thomas's Hospital, London, with a disease that was diagnosed as an anomalous form of combined degeneration of the cord, in some respects resembling Friedrich's ataxia. No suspicion of pellagra arose at the time. He was discharged in two weeks in the same condition as when admitted, and died four months later. The brother of this patient, aged eight years, was admitted to the same hospital in September, 1912, with the history that three months previously he began to have recurring fainting spells. Later he had twitching movements of the limbs and convergent squint. When admitted to the hospital he was able to walk, but his gait showed a mixture of spasm and ataxia. He had a coarse nystagmus and his speech was indistinct. Even when the patient was lying in bed there was moderate rigidity of the arms and legs. He presented a symmetrical erythematous dermatitis of striking distribution which afforded the clue to the nature of his disease. The inflammation involved the backs of the hands and wrists, the orbital regions and bridge of the nose, the nape of the neck and backs of the ears, and, to a slight degree, the points of the elbow. On the face the dermatitis crossed the bridge of the nose, encircled both eyes and spread slightly on to the malar regions. The skin over this area was reddish in color, resembling acute sunburn. The patient died one month after admission to the hospital.

2. The Nervous System in Pellagra.—F. W. Mott made an exhaustive histological examination of the different parts of the nervous system in the latter of the two cases reported above by C. R. Box. There was a slight general diffuse sclerosis throughout the white matter of the cord in all regions, but in certain regions there was a perceptible naked-eye combined sclerosis affecting the direct cerebellar and Gowers's tracts, Goll's column, and the crossed pyramidal tracts. All the posterior spinal ganglion cells showed in varying degrees a marked chromatolysis, swelling of the cell, disappearance of the Nissl granules, except at the periphery, and frequently eccentric position of the nucleus. All the anterior horn cells and their homologues in the medulla and pons showed varying degrees of perinuclear chromatolysis; in some instances the cells were so markedly swollen, and the nucleus was so eccentric, that it appears as if the cell were dead. There was a marked chromatolysis of the cells of Clarke's column. The cells of the cortex showed similar changes.

3. The Natural History of Pellagra.—L. W. Sambon states that he has found this disease endemic in the eastern districts of Scotland and in the Shetland Islands. It appears to be linked to briskly running water just as necessarily as malaria is linked to stagnant water. The author believes that the *Simulidæ*, which are minute, thick-set, dark-colored flies, are concerned in the transmission of pellagra. They have a worldwide distribution and are found as a rule along briskly moving water.

Berliner klinische Wochenschrift.

June 30, 1913.

Influence of Lime Salts on the Constitution and Health.—Emmerich and Loew speak of the gradual recognition of the fact that not only bone and teeth, but heart muscle, glands, nervous system and brain, and so on throughout the sum of organs and tissues all depend on lime salts for their best efficiency. Calcium has been shown by biological reactions to be present in all cell nuclei. In fact the amount of calcium in the animal body varies directly with the nucleus content. Hence glands and lymphnodes contain an amount of calcium much greater than muscles, etc., because of the vastly increased number of nuclei. Calcium is therefore a sort of measure of cell activity, and the chief type of cell activity is connected with enzyme action. These properties are more readily studied in plant life but hold good as well for animal cells. Moreover, if we derive our lime from plant cells the knowledge of the latter becomes of special value. The authors have studied all forms of introduction of lime salts into the organism, and have learned incidentally that while a plain solution of lime chloride usually causes a marked gain in weight, it may exceptionally cause loss. In swine albumin metabolism and nitrogen retention are promoted, but there is a decrease of fat accumulation. The first phenomenon may cause an initial increase in weight, but the second in time overbalances it. To apply the authors' finds to practice one needs only to quote Reinhardt, a recent student of the subject: "Neurasthenic, overworked, and physically depressed persons are so rapidly healed by the chloride of calcium solution, that they could not show sufficient gratitude. They felt as if newly born, full of the zest of life, stronger and more enduring than ever and twenty years younger." Similar results are claimed for dogs. In addition to the use of a solution of anhydrous chloride, of which the patient takes doses representing 1.59 for a long period, the authors recom-

mend a calcium bread and similar products. They believe that the proper use of calcium is the keystone of individual hygiene.

Syphilis and Fever.—Glaser speaks of several types of syphilitic fever, some of which have long been known. He mentions early syphilitic fever preceding the rash, and tertiary syphilitic fever. Aside from these, however, there are types of fever which are irregular and simply indicate mixed infection. The first modern description of sure secondary syphilitic fever is by Guntz and Fournier about 30 years ago. It was held to be present in about 20 per cent. of cases. Many years later Senator sought to differentiate early syphilitic fever from other acute infectious diseases. It should be remarked that the syphilitic fever is not always a reaction preceding the exanthem; for in certain instances the fever is purely symptomatic of certain local lesions. Despite some connection between exanthems and fever the early syphilitic fever cannot be so easily explained (since it is a minority symptom). Pure tertiary syphilis is even more difficult to account for. Much more readily comprehended are the secondary syphilitic fevers which are seen in luetic liver, luetic lungs and the like. Certain fevers in certain patients appear to suggest the possibility of late syphilis.

Münchener medizinische Wochenschrift.

July 1, 1913.

Two Cured Cases of Tuberculous Meningitis.—Reichmann and Rauch report two such cases from Professor Stintzing's clinic. Such cases hold good for themselves alone, for any general successful therapy of this disease does not yet exist. Of the two cases cited, we quote that in the adult first. This patient, aged twenty-one, worked in glass, was admitted to the hospital in a state of mental confusion. History as follows: Patient always well and of sound stock. His illness began four weeks before admission with weariness, headache, and stitch in the side. He continued to work, although somewhat feverish for several days, when he developed fever blisters, cough and expectoration. In six days this petty attack had run its course. Certain symptoms, however, seemed to reappear—chiefly a severe, persistent headache and stiffness of the neck. On this account he was sent to the hospital with the diagnosis of meningitis. Examined at the latter place he was found to be drowsy with fever above 39° C., and high degree of nuchal rigidity. The pulse was but 68. Kernig's symptom was present, but the various reflexes were either absent or but slightly in evidence. Examination of lumbal punctate, when carried out with thoroughness and patience, showed tubercle bacilli abundantly sufficient for diagnosis. By studying these punctates with especial regard to their inoculability to animals, it became apparent that the virulency of these punctates became less and less pronounced. In the second case, in an infant, the diagnosis was made in the same manner. The old clinical diagnosis so commonly discussed was reinforced by the punctate finds. Of interest is the literary research of the authors, which show that up to the present time eighteen cases of tuberculous meningitis had recovered, those of the authors making twenty to date. But, as the authors state, what does this petty salvage signify against the tens of thousands of deaths from this cause in recent years?

Traumatic Thrombosis of the Inferior Vena Cava and Life Insurance.—Weber relates the following case: A robust looking man appeared for life insurance examination, but was seen to suffer from clumps of enlarged superficial veins believed to indicate an obstruction of the inferior vena cava. The urine was clear, and this fact, along with the patient's youth (age twenty-six), permitted his insurance for ten years. At the expiration of this period he was apparently in good health and insurable. Another case of much greater interest was that of a young medical man. In 1884, at the age of twenty-four he sustained a traumatic thrombosis of the inferior vena cava. There resulted a great dilatation of the superficial veins. The cause of the superficial vascular lesion was an attempt to break the short, high hurdle record. Patient at once took to his bed, and developed albuminaria. Bedridden for six months, he rallied and lived for twenty-five years, an invalid. The actual cause of death was tonsillitis, plus sepsis, but in the meantime various veins had become obliterated. Shattock traced the original mischief in all such cases to a laceration of the intima.

Deutsche medizinische Wochenschrift.

June 26, 1913.

Treatment of Cancer with Röntgen Light and Mesothorium.—Krönig and Gauss arrive at the following conclusions in reference to combined radiation therapy, a subject now in much vogue throughout Germany. As far as they have gone the indications are as follows: If cancer is still operable and controllable by sight and touch, we undertake to cure it by combined radiation. If this procedure fails we still have time for radical operation. If the cancer is operable, but not controllable by sight and touch, radical operation may be performed if the percentage chances are in the patient's favor. If these are not favorable, treatment should be by radiation. If the cancer is positively nonoperable the treatment should be intensive radiation, along with any other promising resources. Special resources should be employed to prevent recurrence. Every operation must be followed up by intensive radiation. This is a universal rule, and should be pushed to the limit, even after the average relapse period has expired.

Living Spirochetes in the Brains of Paralytics.—Forster and Tomasczewski refer to the first announcement of the discovery by Noguchi and Moore as to the finding of spirochetes in the cortex in progressive paralysis. Later Noguchi reported forty-eight cases in a total material of two hundred. Corroboration soon came from Marie, Levaditi and Bauchowski, along with Marinesco. All of these were cadaver finds. The methods used were either dark field illumination or silver impregnation. The authors have now greatly advanced our knowledge by results obtained through cerebral puncture in living paralytics. The material was obtained by the Neisser-Pollak technique which is very efficacious in brain studies. One case may be cited as an example: Male, aged forty-eight, with no history of luetic infection. During past eighteen months an obscure psychic alteration, which culminated in a seizure, in which the speech was chiefly affected. From then on progressive evidences of dementia paralytia. There was a cerebral puncture made at the right frontal brain. By dark field illumination numerous mobile spirochetes were seen in the punctate.

On the Applicability of Gelatine Capsules in Drug Administration.—Niculescu considers the general problem of giving medicines by hard coated gelatine capsules which are able to traverse the stomach unchanged. The passage of these capsules is controlled by Röntgen rays. The author mentions the use of iodide of potassium as an index of the absorbability of the capular contents, and discusses other methods of hastening or retarding absorption. His conclusions are expressed as follows: The desideratum in giving medicines in these capsules is that when the contents of the capsules are water-soluble and osmotic the capsules must be thick and resistant; while if the contents are not water-soluble thinner-walled capsules will answer.

Insurance Medicine.

The Medical Director as a Substantial Factor in the Establishment and Development of a Legal Reserve Life Insurance Company.—In the relation mentioned in the title of this paper, the successful medical director is a very important person and in some respects may be a very different person from one who would be very successful as the medical director of an old and established company. Mr. I. M. Hamilton, President of the Federal Life Insurance Company, Chicago, Ill., says that the medical director of an old and established company should be able to conduct the affairs of the medical department of his company so as to conserve the efficiency of an organization already established; the medical director of a company in the process of development should be able to organize as well as conserve, and unless possessed of this ability will be a substantial but deterrent factor. The director of a company about to be established is often selected while the company is in embryo and his selection is more often because of his supposed influence with others, or his ability to invest money or because of a personal "pull," than for any special qualification or previous experience properly to perform the duties of the position. Fortunately, all medical directors are not selected under such circumstances, and the great majority of those so appointed soon recognize the inevitable and resign or learn to perform their duties to the credit of their companies and themselves. Mr. Hamilton considers that the incipient medical director is much handicapped compared to members of other professions by the fallacies of his professional education and the ethics of his profession. It is necessary for him to discard many of his ideas before he is prepared properly to work out the business propositions which come before the medical department of his company for solution. As a physician, his unbusiness-like inconsistencies are frequently embarrassing after becoming a medical director. During the embryo stage of this type of insurance company, the medical director, to be of most value to his company, in addition to other necessary qualifications, should possess a large amount of patience and tact. He should have courage and dignity, discernment and organization ability, and the more personal magnetism the better. He should be constructive. The responsibilities of the medical director are grave ones and it requires courage and decision to meet them properly and promptly. He should bear in mind and be inspired by the thought that he is participating in establishing a worthy and lasting institution, to serve humanity long after he is gone; that it is in his province to "reject" and "approve," and that he can soften the disappointment to the applicant and the agent, not overlooking the wisdom of offering applicants not standard, such other forms of insurance as he believes his company with safety may issue. His dignified and congenial attitude towards the company's agents together with these other qualifications will make him an appreciated part of the constructive force in the establishment of his company and the conservation of its subsequent interests. Another important duty devolving on the medical director of a growing company is the selection of its local examiners and inspectors. Improvement can often be made along these lines, and the medical director should keep his examiners impressed with the true relations existing between them and the company employing them. In the selection of local examiners preference should be given to experienced physicians of deserved and established reputation, who understand the merits of legal reserve insurance. This does not mean that the young physician of high character, ambitious to become an examiner, should be tabooed, but his appointment should be a temporary one until he shall have proved his fitness for the work. A man of character and superior medical attainments, even though educated in an inferior school is to be preferred to a man of inferior ability, though educated in a superior school. The medical director who handles his examiners and agents with tact and discretion is a decided asset to his company, for harmony and not friction means benefits to all concerned. Promptness in decisions, whether favorable or unfavorable, and without carelessness or inefficiency is another link in the chain of requirements which hold a medical director in the respect and desire of his company. The medical director having the last word, so to speak, in cases of disagreement between himself and his agents can afford, and it is his duty to be, generous. Agents should be treated as patients, and not antagonized.—Report of the Medical Section, American Life Convention, February, 1913.

Effects of Tobacco Smoking.—That the effects of tobacco smoking are regarded as more or less serious according to the experience of the physician coming across many cases, was shown in a discussion among the members of the Life Assurance Medical Association, at a meeting held in London on January 15, 1913. Dr. Lees, while not a member of the Association, when asked for his opinion, said he had divided his results obtained on observation of many cases of habitual smoking, into two classes. In the first class, he placed young adults in which the early symptoms were signs of poisoning; in the second class, men of later life, showing signs of degeneration. In the first class, the chief symptom was the dilatation of the heart. In examining many cases of incipient pulmonary tuberculosis, Lees found that while in women the heart was always small, in young men, who were smokers, it was large. The border of the left ventricle in them was always outside the nipple line. After rest and total abstinence from tobacco, the heart resumed its normal size. In many of these cases there were no physical signs referrable to the heart, and the dilatation was only found after careful physical examination. Dilatation of the stomach frequently accompanied the first condition, but they were found independently of each other. In later life many conditions of degeneration are produced, not only by well-known causes, but also by the decidedly deleterious influence of tobacco, among these, the emphysema of men from 50 years old and upwards, which comes on gradually and is rarely the result of long-continued coughing. Often there is no history of cough at all, but a chronic condition slowly progressive in men of this age, who have been inveterate smokers of many years' standing. Chronic conditions of the heart and vessels, "intermittent claudication" and heart failure have been found in men who have given no history of other causes for these conditions, such as renal disease, syphilis, etc., but who have been heavy smokers. Inveterate smoking has seemed to play an important part in the causation of angina pectoris, as most cases give a history of this indulgence.

Book Reviews.

Practical Physiological Chemistry. A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and Science. By Philip B. Hawk, M.S., Ph.D., Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. Fourth Edition Revised and Enlarged. With Two Full-Page Plates of Absorption Spectra in Colors, Four Additional Full-Page Color Plates, and One Hundred and Thirty-seven Figures of Which Twelve Are in Colors. Price $2.50. Philadelphia: P. Blakiston's Son & Co., 1913.

It is hardly necessary at this time to speak of the many excellencies of this work, for it has already long been known as one of the most practically useful of the many on the subject. The new edition comprises an unusual amount of new matter, so that the volume has been considerably increased in size, and many illustrations have been added. The chapters on the enzymes, carbohydrates, proteins, blood and lymph, feces, putrefaction, and quantitative analysis of urine have been enlarged and in the latter section a number of new methods have been included. An addition of importance in the section on blood counting is the full description of Burker's technique, which apparently represents the one great improvement in this direction that has been made in years. The book has now been so carefully revised and worked over that it is difficult to see how it could further be improved.

Organic Chemistry, Including Certain Portions of Physical Chemistry for Medical, Pharmaceutical, and Biological Students. With Practical Exercises. By Howard D. Haskins, A.B., M.D., Associate Professor of Organic Chemistry and Bio-Chemistry, Medical Department, Western Reserve University. Second Edition. First Thousand. Price $2.00 net. New York: John Wiley & Sons, 1913.

In this book the reader will find such facts of organic and physical chemistry as have an essential bearing on medical science. The arraignment and style are clear, and the small size of the volume and its large print combine in making it attractive. The work can be recommended to the student as a really interesting introduction to what is too often considered a dry and repellent subject.

A Text-Book of Physiology. By Isaac Ott, A.M., M.D., Professor of Physiology in the Medico-Chirurgical College of Philadelphia; Ex-Fellow in Biology, Johns Hopkins University; Consulting Neurologist, Norristown Asylum, Pa.; Ex-President of American Neurological Association, etc. Fourth Edition, Revised and Enlarged. Illustrated with 434 Half-Tone and Other Engravings, Many in Colors. Price $3.50 net. Philadelphia: F. A. Davis Company, 1913.

In this new edition the author has added a considerable amount of new material. There are plates showing the movements of the stomach and intestines; the chapter on the Internal Secretions has been largely rewritten; Abderhalden's new test for pregnancy is explained; a description of the heart in Stokes-Adams' disease is included; and, as a rule, the latest facts in physiology have been recognized. The preface tells us that the pineal gland and gonads have been considered; but we are unable to find the latter in the index. Physiological technique is wisely omitted; it should be learned in the laboratory, and not from a text-book. The volume is only one-half the size of the second edition, but it contains about one hundred more pages. In its present form it will bear comparison with the best one volume works on the subject; and for the practitioner it will prove a very useful book.

An Introduction to Chemical Analysis. For Students of Medicine, Pharmacy, and Dentistry. By Elbert W. Rockwood, M.D., Ph.D., Professor of Chemistry and Toxicology and Head of the Department of Chemistry in the University of Iowa; Author of "A Laboratory Manual of Physiological Chemistry." Fourth Revised Edition with 20 Illustrations. Price $1.50 net. Philadelphia: P. Blakiston's Son & Co., 1913.

This book is well known as one of the best works on Analytical Chemistry for junior students. The present edition shows but few changes; some errors have been corrected, and a few of the more difficult methods have been simplified. There are two useful chapters on the sanitary examination of water and the detection of poisons. The author makes no attempt to produce a complete manual, but wisely contents himself with providing a most useful introductory work.

The Plant Alkaloids. By Thomas Anderson Henry, D.Sc. (Lond.), F. C. S. Superintendent of Laboratories, Scientific and Technical Department, Imperial Institute. Price $5.00 net. Philadelphia: P. Blakiston's Son & Co. 1913.

This volume is a perfect cyclopedia on the vegetable alkaloids. Of the importance of these bodies in medicine and chemistry there is no question; and the reader will find here an account of the properties, chemistry, occurrence, physiological action and methods of estimation of all the more important members of this group. The constitution of the alkaloids is given wherever it is known, and the author devotes a brief space to the discussion of the interesting questions concerning the method of formation and the function of alkaloids in plants. The book is well furnished with references to chemical literature, and many of these references are to periodicals and publications as late as 1912.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia; Assisted by Leighton F. Appleman, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. March 1, 1913. Price $6.00 per annum. Philadelphia and New York: Lea & Febiger.

The present number of Progressive Medicine contains five articles. Surgery of the head, neck, and thorax is contributed by C. H. Frazier; Infectious diseases, including rheumatism, pneumonia, and influenza, by J. Ruhrah; Diseases of children, by F. Crandall; Rhinology and Laryngology, by G. B. Wood; and Otology, by A. B. Duel. Attention may be called to the valuable résumé of the work of Kopetzky and Haynes on Meningitis, on page 43; and a much fuller account of the same on page 312. Many readers will be apt to miss the latter reference, as they would hardly think of looking for the surgical treatment of meningitis under the heading of Otology.

Clinical Laboratory Methods, A Manual of Technique and Morphology Designed for the Use of Students and Practitioners of Medicine. By Roger Sylvester Morris, A.B., M.D., Associate Professor of Medicine in Washington University, St. Louis. Price $3.00 net. New York and London: D. Appleton and Company, 1913.

Most physicians are more or less familiar with the significance of the majority of clinical laboratory tests. There are very few, however, who are able to retain in their memory the details of these tests unless they are so placed that laboratory work constitutes a large portion of their daily routine. There is little to be gained by an attempt to remember all these details and the busy physician needs his time for more important things. This volume is a manual of laboratory technique and morphology, dealing merely with methods and with morphological elements which are of diagnostic importance. It gives in detail the means of detecting the abnormal in urine, gastric contents, feces, blood, sputum, and puncture fluids. Many valuable though minute technical details are included, while the significance of the abnormal finding is not discussed. The serological reactions and the more complicated chemical methods are not included. The work is carefully done and the book is therefore a valuable one. With this at his elbow any physician should be able to perform any of the clinical laboratory tests with ease. There is one typographical error which is of importance. On page 66, Solution B of Arnold's reagent for diacetic acid is made to consist of sodium nitrate. It should, of course, read "sodium nitrite." With this exception the press-work is excellent. The book can be highly recommended.

Die Schönheitspflege. Für Ärzte und gebildete Laien. Dargestellt von Dr. Orlowski, Specialarzt in Berlin. Dritte Auflage. Price 3 Mks. Würzburg: Curt Kabitzsch, 1913.

This brochure considers all the methods of the "beauty-doctor" and handles them in excellent shape. The proper way to attain whatever beauty there may be possible for the individual is carefully pointed out, as well as the dangers attendant upon many of the practices recommended by advertisement. The chief drawback for the American reader is that many of the preparations are local ones and would probably be obtained in this country only with considerable difficulty. The popularity of the pamphlet may be judged from the fact that this is the third edition issued within six years.

Society Reports.

TUESDAY CONFERENCES OF THE NEUROLOGICAL INSTITUTE.

FIRST DIVISION—DR. JOSEPH COLLINS.

Paralysis of Hypoglossal Nerve Due to Caries of the Occipital Condyle.—Dr. C. B. CRAIG presented this case. Paralysis of the twelfth cranial nerve is a symptom that the neurologist frequently encounters. It is usually associated with hemiplegia on the same side and is in such instances dependent upon vascular lesion in the motor pathway above the motor decussation. But paralysis of the hypoglossal nerve peripheral to its nucleus is comparatively rare, the more so if it be the only cranial nerve involved. Of the seventy-nine cases of hypoglossal paralysis collected by Ascoli only one-third had a peripheral cause. Lüschow and Oppenheim have each reported a case similar to that which I present.

The patient, a Jewess, 52 years old, born in Turkey, is married and has four children. Her previous medical history is uneventful except that three years ago she underwent a gynecological operation for uterine fibroid. While convalescing from the operation about ten weeks later she had two attacks of "stiff neck" two weeks apart and each lasting seven or eight days. The pain and stiffness on each occasion were confined entirely to the right side of the neck posteriorly.

Since that time she has been troubled with intermittent attacks of mild pain in the right suboccipital region accompanied by a "crackling" on rotating or nodding the head. Three months ago the pain recurred with increased intensity and has gradually got worse.

When first seen on March 23, 1913, the patient had in addition to the pain almost complete fixation of the head and neck. This fixation was caused by the pain attendant on movements, especially the nodding motion. There was marked tenderness over the right suboccipital area and the region below the ear. There was slight drooping of the right angle of the mouth. When the lips were pursed there was distinct weakness of the sphincteric power of the right half of the mouth. No other facial weakness was demonstrable. The tongue as it lay on the floor of the mouth was heaped up on the left side, the right side being broader and thinner. The raphe curved to the left and the tip was directed in the same direction. She could with difficulty touch the upper right row of teeth with the tip of the tongue, and on protrusion the body of the tongue deviated sharply to the right while the tip turned off the left. There was no fibrillary tremor. On palpation the right half of the tongue felt soft and flabby.

When the patient was admitted to the hospital on the following day she had a temperature of 102° F. The leucoytes numbered 15,000. Physical examination showed an indurated area with local heat below the right mastoid, with all the appearance of a ruptured purulent mastoiditis. There was, however, no reddening of the external auditory canal nor of the drum membrane. An incision was made the same day by Dr. Elsberg just below and in front of the right mastoid, deeply into the neck, and a small collection of pus, close to the anterior portion of the occipital bone, was liberated. A probe passed into the wound came in contact with denuded and carious bone. An *x*-ray picture later showed, in the opinion of Dr. Archibold P. Evans, a mild grade of disintegration of the right condyle, the vertebræ being all quite normal. Cultures made from the pus developed *Staphylococcus aureus*. There was no evidence of involvement of the spinal accessory nor vagus nerve. The evident cause then of the paralysis of the right hypoglossal nerve was a carious condition of the right occipital condyle involving the nerve at its point of escape from the skull, namely the anterior condyloid foramen. This case is particularly interesting inasmuch as it tends to establish the position, maintained by Tooth and disputed by Oppenheim, *i. e.* that the hypoglossal nerve takes part in the innervation of the orbicularis oris muscle.

Operation for Tumor of the Hypophysis.—Dr. ELSBERG presented from the First Division a patient upon whom he had performed a frontal craniotomy for tumor of the hypophysis with threatened blindness. The patient was a man of 31, who had been treated for some eye trouble for two years until it was recognized that he had a temporal hemianopsia. When the patient was admitted into the Neurological Institute, he had only slight light perception in the nasal side of the right eye, and complete temporal hemianopsia on the left side. By *x*-ray the sella turcica was found much enlarged. The hypophysis was exposed by the transfrontal route as described by Frazier, and an excellent exposure of the sella turcica and contents obtained. The hypophysis was the site of a large tumor of which a part was removed with a sharp spoon. Convalescence from the operation was uneventful. Improvement in the left eye was noticed by the patient on the day after the operation, and has steadily continued. The last perimetric charts show a very marked increase in the field of the left eye for all colors.

SECOND DIVISION—DR. FREDERICK PETERSON.

Aplasia of the Lenticular Nuclei.—Dr. FOSTER KENNEDY presented this case: M. B. female, age 8 yrs. was seen in the out patient department of the Neurological Institute on the 5th of March, 1913. The parents complain that she is unable to walk or control her arms or to speak properly. She is an only child, and was delivered after seven months' term; no instruments having been employed, in delivery. The arms and legs at two years of life were stiff and allegedly incapable of being moved volitionally. At the age of three years the child began to move both her arms and legs and her power over her limbs has improved up to the present time. There is no real palsy but adequate power is enormously interfered with by reason of marked hypotonus of all the muscles of the body, to which disadvantage is added a bilateral tremor affecting both the arms and legs, of coarse and irregular nature. At times this tremor is replaced by movements of severely choreiform nature. The cranial nerves are normal. Emotional instability marked but emotional expression somewhat limited, owing to her smiles being slow to develop, and spastic. The mouth is held open, and dribbling of saliva is almost constant. There are no sensory changes whatever. The knee jerks and the ankle jerks are not obtained, a condition which may be perhaps explained by the high degree of hypotonus present in the musculature. In the moments of relaxation of the abdominal muscles the superficial abdominal reflexes have been obtained on both sides. The plantar reflexes are indefinite in type. The great toes by reason of hypotonus are held normally in an acutely extended position. On stimulation of the soles these toes are flexed and again rapidly extended. Attempts at walking are quite unsuccessful;—muscular hypotonus, tremor, and choreiform movements combining to make progression impossible. With difficulty can any object be grasped by either hand for similar reasons. Speech is almost unintelligible. Vowel sounds are fairly well expressed, but apparently owing to the spasticity of the muscles involved she is unable to approximate properly the tongue and the various parts of the buccal cavity necessary for the intelligible production of consonants. When asked her address which is 281 Monroe Street, she gives it promptly and to the listener knowing the proper answer it is clear from the

vocalization and rhythm of the sounds that she is attempting to give correct information. Similarly in many tests she has displayed acute intelligence. No intelligence defect can be demonstrated. Special senses are all normal, and in view of the criticism that this case may be one of agenesis of the cerebellum it may here be stated that no nystagmus has ever been demonstrated,—that the dysarthria is much more marked than is found in that affection; and that the general increase of muscular tonus is opposed to such a diagnosis, defective cerebellar control being invariably associated with a diminution rather than with an increase of muscular tonicity.

Some years ago this case would have passed more or less unnoticed in most outpatient departments with the label of Little's disease placed upon it; but the condition described by Little embraces many different clinical types and in most of these cases marked mental defectiveness is present.

In March, 1912, Wilson described a series of 12 cases in which bilateral softening of the lenticular nuclei was demonstrated on autopsy together with a multilobular hepatic cirrhosis. The latter pathological condition did not manifest itself by any symptoms during life. But the symptoms consequent upon the ganglionic degeneration were, briefly, marked hypertonus of all voluntary muscles with the exception of the extrinsic muscles of the eyes, bilateral irregular tremor, marked dysarthria, emotional instability, the mouth being held agape with dribbling of saliva. Not until the very last stages of the disease was any intelligence defect demonstrable. In the case under consideration, it is not alleged that the morbid condition is one of those described so excellently by Wilson in which the condition occurred subsequent at the earliest to the 10th year of life, and which progressed in all cases to a fatal termination. But the author of that paper by his clinical observations and anatomical examinations of the cases observed has succeeded in demonstrating a symptomatolgy referable to the lenticular nuclei. A premature child bearing from birth the signs found in Wilson's cases in which these nuclei were demonstrably degenerate makes it highly probable that in such a case these nuclei were either congenitally diseased or, much more probably, congenitally deficient. In such a hypothesis there is nothing inherently improbable or fantastic in view of the many cases of aplasia of various cranial nerve nuclei which are on record.

THIRD DIVISION—DR. PEARCE BAILEY.

A Case of Drug Delirium.—Dr. Louis Casamajor presented this patient, a married woman of 36 years, who was admitted to the service of the Third Division on April 15, 1913, in a state of agitation and excitement. The history was obtained from the nurse who had brought her to the Institute from a small town in a neighboring state. In the family history the only prominent incident was the fact that the patient's mother had suffered from a psychosis at one time. The personal history is negative. The patient had had six children, five of whom are living and well and the sixth was a still birth at term. No history of venereal or other disease.

For six months before admission to the hospital the patient had been treated for "heart disease" and had taken numerous drugs: About two weeks before the onset of her persent trouble, she began taking a proprietary mixture of bromides and hyoscyamus on her physician's advice. We have been unable to determine the exact composition of this mixture but judging from the fact that the dose was one teaspoonful t-i-d., the amount of drug taken could not have been very great. Two months before her admission to the hospital, the family noticed that the patient was becoming very absent minded and a bit quarrelsome in accusing others of not doing their work. Following this she became confused and talked in a rambling disconnected fashion, jumping rapidly from one subject to another. As her condition became worse she expressed peculiar ideas about herself, at times stating that she had a large tumor in her abdomen, and at others that her head had been crushed in. Frequently she heard imaginary voices and spoke of seeing people in her room who were not there. She slept and ate very little and had lost considerable weight.

Physical examination on admission showed a thin, poorly nourished woman of early middle life who weighed 104 lbs. Her pupils were widely dilated and reacted sluggishly to both light and accommodation. All superficial and deep reflexes were active and equal throughout. The heart showed typical signs of a fairly severe mitral stenosis. The urine and blood were negative.

Mentally the most prominent features in this case were the confusion, hallucinations of sight and hearing, and the dream-like ideas. She knew she was in a hospital in New York, but could not name the day or date, yet she knew that the year was 1913. She made mistakes in giving her age, the date of her birth and other more recent dates. She stated that she had been operated upon—the doctor had made a cut in her abdomen and removed a number of sticks about 2 inches long tied to one another with strings. She was told they were sticks of dynamite. Her talk was distinctly flighty with word and sound associations and she was continually being distracted by things in her environment and by hallucinations of sight and hearing. Paraphasia was not prominent. On one occasion she said: "I sneezed today and everything ran out of me in the bed and my palate has gone down again. My heart is in pieces and part of it is in my shirt pocket. I turned over and my belly button came out but it did not go very far. It only went on a vacation. . . . People shoot things at me and they go through me; they shoot glass or something at me. A doctor operated on me and then he took a couple of lambs or pigs, now which it was I don't know, and put them in my insides just because I was decayed."

She continued to express ideas of things being shot into her, of animals being put in or taken from her body. At times she claimed that her husband and children were murdered and their bodies were down stairs. Her daughter was killed each day and buried and dug up and murdered the next day. Her affect reaction seemed very insufficient as she showed little sorrow or anxiety while telling of these things.

With the diagnosis of drug delirium made, very active eliminative treatment was instituted consisting of hot baths and packs, saline diuretics, and cathartics, together with forced feeding. After about ten days the delirium began to recede. The patient slept better and was much quieter during the day. First she ceased her flighty distractable talk and then the delirious and dream-like experience gradually receded from her thought stream and the patient presented for a few days a pure hallucinosis mostly in the auditory sphere. As these hallucinations subsided she would manifest excitement when she heard children's voices in the street for she thought they were the voices of her own children who were being in some way injured.

Mental examination on May 10 showed a normal mentality. Her memory was good for events happening up to within about one month of her entrance to the hospital. From this time on her recollection is increasingly hazy. She retains practically nothing of her trip to the hospital. Beginning with about May 1 her memory returned and now there remains nothing of her psychosis but the circumscribed partial amnesia for the period of her delirium. She is now ready to be discharged as cured.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held April 15, 1913.

DR. LINSLY R. WILLIAMS IN THE CHAIR.

Aneurysm of the Aorta, Showing Results of Antisyphilitic Treatment.—Dr. G. REESE SATTERLEE reported this case. The patient was a man, 50 years old, a chef by occupation, and married. As a child he had measles and in 1874 he had yellow fever. Twenty-five years ago he had a severe attack of jaundice with pain; this illness was of nine months' duration and the jaundice lasted nearly two years. His habits during the latter part of his life had been good. Thirty years ago he had an attack of gonorrhea with a chancre, said to be a soft one. He had noticed no eruption and did not know that he had syphilis. There was no further history of acquired venereal disease. His present illness began about three years ago with indigestion, for which he was treated in the out-door department of the New York Hospital. At the same time he had pain in the back and dyspnea. He was then treated in the tuberculosis clinic of the Department of Health and his condition was diagnosticated as pulmonary tuberculosis. He was sent to Otisville, where the pain became so severe he could not work. On further medical advice, he went to Denver and later to Colorado Springs. There he became much worse, with severe pain in the back and dyspnea. He said that he was told he had pulmonary tuberculosis. In May, 1911, when Dr. Satterlee first saw him, he came in complaining of hoarseness and aphonia. He also had severe pain in the left side of the chest, in the epigastrium, and in the left shoulder. The pain was continuous and it prevented him from lying on his back. He had dyspnea on exertion, but no cough. A laryngeal examination showed a paralysis of the left vocal cord, but no local syphilitic manifestations. The physical examination showed the patient to be a man of good frame, but considerably emaciated. The superficial veins on the anterior surface of the left side of the chest and on the left shoulder and arm were engorged and tortuous, with thickened walls. The heart showed a moderate degree of hypertrophy with normal action and sounds. There was a distinct area of dullness, 2½ inches in diameter, in the first and second interspaces, merging with the area of cardiac dullness. No murmur, pulsation, nor thrill was evident. The left radial pulse was absent. The eyes were normal. The Wassermann complement fixation test was positive. A tentative diagnosis was made of thoracic tumor, near the arch of the aorta, possibly an aneurysm, and an active tertiary syphilis. Dr. Le Wald, at the Edward N. Gibb *x*-ray laboratory, made a stereoscopic radiograph of the chest, which revealed an interesting condition. The accompanying plate showed a round tumor mass, situated in the neighborhood of the arch and beginning portion of the descending thoracic aorta. The outline of the shadow was smooth and spherical, the density of the shadow less than that of the aorta. Subsequent radiographs, both anteroposterior and lateral views and fluoroscopic examination, failed to fully convince them that the tumor was only an aneurism. There was, however, a distinct aneurismal dilatation of the thoracic aorta at the level of the lower third of the heart, extending below the lower third of that organ. The lungs showed no evidence of tuberculous deposits. He had no sputum to be examined for tubercle bacilli. A few doses of salicylate of mercury were given intramuscularly and then 0.4 gram of salvarsan suspended in oil of sesame was injected into the substance of the gluteal muscle. The injection of the salvarsan caused considerable pain, but the results were very satisfactory. Two and a half days after the administration of the salvarsan, the patient experienced a feeling of return of the circulation of the blood in the left forearm and hand. Examination showed the left radial pulse to be present where it had previously been absent. The voice also began to steadily improve and the man's general physical condition showed a vast improvement. One grain of salicylate of mercury was given intramuscularly, twice weekly, and potassium iodide up to the toleration point until August 5. On this date 0.3 gram of salvarsan was given intravenously, and this was followed by a decided feeling of improvement in the general condition and the pain. The urine had always been normal and the blood-pressure averaged 160 mm. of mercury. On October 13, the laryngeal examination showed a slight weakness of the left vocal cord, a condition of decided improvement. The Wassermann test on this day was negative. The heart had been acting well, as evidenced by normal polygraph tracings. The diagnosis at the present time seemed to point to an aneurism of the descending thoracic aorta and to one of the arch, with a syphilitic deposit in the neighborhood. It seemed probable that the pressure on the left subclavian artery and on the left recurrent laryngeal nerve was caused by the aneurism of the arch, indirectly through the surrounding mass. This pressure must have been relieved by the action of the antisyphilitic treatment in resolving some of this deposit, presumably syphilitic in nature. It hardly seemed probable that the size of the aneurism could be much diminished in so short a time. In comparing the early and late radiographs, no marked diminution in size of the aneurism could be noted. Salvarsan was undoubtedly a powerful agent in the relief of this man's condition, but had to be administered in a small dose and with care, and combined with treatment with mercury and the iodides. He felt that in these cases Ehrlich's valuable remedy should not be neglected, and if given in repeated small doses would obviate the possible danger from a large dose in aortic disease and aneurism. The presence of an active syphilis should naturally be ascertained. The blood-pressure, if it did rise after the administration of salvarsan, was not elevated more than 5 mm., so that danger from this source could possibly be eliminated. Up to this date, April 15, the patient had seventy-eight intramuscular injections of mercury salicylate, 1 grain each. He was able to do light work and had lived a few months last summer in Colorado with no discomfort. The blood-pressure was now 150 and there was no pain present.

A Hitherto Undescribed Form of Polycythemia and Its Possible Relation to Duodenal Ulcer, Chronic Pancreatitis, and a Disturbance of Internal Secretions (Suprarenal).—Dr. GEDIDE A. FRIEDMAN read this paper. He said that polycythemia, polyglobulia, erythemia, and erythrocytosis were the usual terms for increased number of red cells, but the two latter terms were fittingly chosen in analogy to leukemia and leucocytosis. If the number of red cells exceeded 1,500,000, the condition of polyglobulia could be spoken of. A marked increase in erythrocytes might occur physiologically in newborn children and in adults who were living in high altitudes, and pathologically in starvation and in losses of fluid from the body as from persistent vomiting, profuse sweating, severe diarrhea, etc. Cholera asiatica might serve as the best instance of the occurrence of polyglobulia due to losses of body fluids. A numerical increase of red blood corpuscles occurred in congenital and acquired heart disease with disturbed compensation, in emphysema, and in edema of the lungs. Poisoning with phosphorus, arsenic, or carbon dioxide might also lead to the condition of polyglobulia. Polyglobulia also occurred in patients with reduced intake of fluid, as occasionaly in chronic constipation, gastrosuccorrhea, and obstructive jaundice. The causes of most polycythemias remained obscure. The hyperglobulia was, according to Osler, probably compensatory to lack of oxygen in the air, and there was an increased activity of the bone marrow. In true erythremia this same increased activity of the bone marrow was present. Vaquez-Osler disease was, therefore, considered as a primary lesion of the bone marrow, just as leucemia was an affection of the leucoblastic elements. But the immediate cause of the hyperactivity had not yet been established. Their material consisted of 14 patients from private practice, and 11 from the Vanderbilt Clinic, 23 being males and 2 females. The ages ranged from 19 to 57 years. All of the 25 patients complained of the usual symptoms of chronic indigestion and of attacks of pain. The paroxysmal pain dated back mostly for years, and in a large number constant pain was also complained of. Jaundice could not be elicited from a single history. Objectively, there could be demonstrated in all the cases tenderness of different intensity to the right of the epigastrium, in the continuation of the right parasternal line somewhat above the navel; in but a few instances tenderness was found also somewhat to the left of the navel; in one patient there was also tenderness in the appendicular region. In one of the patients was neither liver border nor the gallbladder palpable, nor was the spleen enlarged. There were no tender spots characteristic of gallstone disease, nor of gastric ulcer. Dr. Friedman gave the abstracts of the histories of several cases and then offered the following conclusions: (1) Polycythemia was apparently a frequent phenomenon in cases of duodenal ulcer, proved such by operation, or answering the clinical syndrome erected by Moynihan and others. (2) No such phenomena were seen in gastric ulcer nor in other abdominal conditions. (3) Injections of adrenalin in such patients was followed by a transient diminution in the red cells, but soon afterward the polycythemia asserted

itself. (4) The injections of suprarenal extract in dogs produced a polycythemia which apparently was due to a lesion of the bone marrow. He assumed that the causes of polycythemia in his cases were intimately connected with the causes of duodenal ulcer, and might be due to some alteration in the secretion of the suprarenals. (5) It might be assumed that duodenal ulcer was a trophic disorder due to some disturbance in the secretion of suprarenal extract. His theory was that suprarenal extract in some cases acted harmone-like in a specific manner upon the vessel of the duodenal mucosa and produced the changes that finally led to the appearance of ulceration.

A Case of Amebic Colitis Treated by Emetine Hydrochloride.—Dr. William Van Valsah Hayes reported the case of a man, twenty-one years old, who had suffered from intermittent attacks of dysentery for a year and a half. This was found to be of amebic origin. The patient was put to bed and placed on a light diet. He was given one-half a grain of emetine hydrochloride by hypodermic injection twice a day for three days, and once a day for seven days longer. The symptoms of dysentery disappeared after the third day. The patient was allowed out of bed after two weeks, had steadily improved, and had gone to work.

Visualization of Obscure Lesions of the Gastrointestinal Tract by Means of the Röntgen Rays.—Dr. Alfred F. Holding said that of the five senses, sight was the most acute. Sight applied to the diagnosis of gastrointestinal lesions by means of the Röntgen rays. Concrete examples with definite case histories proved by operation or autopsy finding were reported in dental lesions, in intrathoracic lesions, and in gastric and duodenal lesions. X-ray pictures were shown.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held February 27, 1913.

Dr. George G. Ward, Jr., in the Chair.

Acute Appendicitis, Four Days Post-Partum, Operated Upon Under Spinal Analgesia.—Dr. Sidney D. Jacobson presented a patient who had had a spontaneous delivery. Four days after labor she complained of severe pain on the right side and she had a temperature of 104° F. Upon examination she presented all the signs of a ruptured appendix. Dr. Howard Lilienthal agreed with this diagnosis. The woman also had a very severe bronchitis and a racking cough. Under spinal anesthesia the abdomen was opened and a considerable quantity of sero-pus was seen in the pelvis. The appendix was found buried in a mass of adhesions and inflammatory products and it was believed that an attempted removal of this extensive mass, even if feasible, would entail too much risk to the patient; accordingly the mass was broken into by the finger and a rubber drainage tube passed down to it. The abdominal wound was closed by layer suture in the customary manner except that on account of the cough and danger of rupture of the abdominal wound the fascia was sewn up with two rows of sutures, the first being a row of mattress and the next a running stitch over the cut edges. The patient experienced absolutely no pain during any part of the operation, and she made a splendid recovery in spite of her dreadful cough. It was a pleasure to note the relief experienced with spinal anesthesia; one did not have to contend with a patient straining and forcing her intestines out of the wound. There was a total absence of symptoms referable to the stomach and intestines after operation. After briefly considering the evolution of surgical anesthesia Dr. Jacobson said that it was admitted that inhalation anesthesia was the best for general purposes. However, it was by no means a perfect method and left much to be desired in point of comfort and safety to the patient, and in certain cases was distinctly contraindicated. Advanced diabetes was a condition in which inhalation anesthesia was especially dangerous. If coma supervened it usually meant the death of the patient. Ether could not well be used in warm climates and must be used with extraordinary care in the presence of a gas or other flame, or fire, for fear of an explosion. Certain other general anesthetics could not be used for prolonged operative procedures on account of the short duration of the anesthesia produced. Ether, known as the safest anesthetic, had a distinct mortality rate of its own; as to the exact figures, authorities differed. Keen placed the death rate at 1 in 16,000, while Reclus placed it at 1 in 7,000. Ether was not to be used in the presence of arterial degeneration or aneurysm for fear that the increased blood pressure caused by it might bring about rupture of a blood vessel. It should be voided in acute nephritis, certain operations on the abdominal organs where straining or post-operative vomiting might have serious results, and certain operations upon the brain. It was not suited for operations upon the nose and throat and was contraindicated by the presence of bronchiectasis, emphysema and pulmonary tuberculosis. Alcoholic subjects took ether badly. Chloroform had a conceded mortality of 1 in 2,300 anesthesias. Its use was contraindicated in heart affections with weakness of that organ. Myocardial degeneration, cardiac dilatation, conditions like exophthalmic goiter, asthma, or emphysema, which threw too much strain upon the heart, precluded the use of chloroform. Chloroform was a very dangerous anesthetic in aortic regurgitation, in the lymphatic habitus, and in subjects worn out by prolonged suppuration or cachexia. It followed that inhalation anesthesia was sadly in need of further improvement urged on by the constant necessity of a method of destroying pain without loss of consciousness, experimentation was still going on. Toward this much desired end the discovery of the local anesthetic action of cocaine by Dr. Koller in 1884 was a most valuable contribution. Spinal anesthesia had also been called intradural, subarachnoid, and lumbar anesthesia. Insensibility to pain was produced by the injection of certain substances of the cocaine type into the subarachnoid space of the spinal canal; the region below the spinal segment thus treated became paralyzed as to sensation and motion for a time varying from one-half to two hours. The after effects varied with the drug injected and especially the size of the dose. Leonard Corning of New York was the first to experiment with spinal anesthesia; while he published the results of his work in October, 1885, Bier was to be credited with being the first to intentionally cocainize the spinal canal for surgical purposes. This he appeared to have done without knowledge of the experimental work on animals done by Corning fourteen years before. Bier had done more than any one toward perfecting this method and eagerly tried the newer remedies like stovain, alypin, novocain, etc. In America, Simon Marx, Crile, and Bainbridge were entitled to special mention as pioneers. Babcock administered spinal anesthesia in about 3,500 cases of general surgery, gynecology, and obstetrics. The first spinal anesthesia was used in obstetrics in Bumm's clinic at Basel in 1900. Dr. Jacobson said he had a strong leaning toward the use of stovain for spinal anesthesia, more especially on account of its antiseptic properties. He used the 10 per cent. alcoholic solution containing 0.04 of the drug. In careful hands selected cases would do well by this method of anesthesia. It had its limitations and was not to be used indiscriminately; it had its mortality rate. The main contraindications to its use were extreme debility whether due to hemorrhage, sepsis, or long standing disease, and especially cases with very low blood pressure. Its great field of usefulness would therefore be in those cases of disease of the heart, lungs, or kidneys, in which the use of the vapor anesthetics was contraindicated and more especially in major operations anywhere below the nipple line.

Dr. George Gray Ward, Jr., asked if Dr. Jacobson had used central instead of lumbar spinal anesthesia; abroad he noticed they used this method a great deal. He had also noticed that the injections were usually preceded by a hypodermic of morphine and when the patients were brought into the room they were more or less in a state of stupor.

Dr. Sidney D. Jacobson replied that he had used that method in some gynecological cases and in one case of ectopic gestation that had ruptured. In using the central method one should go high up if he wished to desensitize the parts.

Large Papillary Adenocarcinoma of the Ovary Complicating Labor Removed During Puerperium, with Recovery of the Patient.—Dr. Sidney D. Jacobson reported this case. The patient was a Roumanian, twenty-two years old, and in the last month of pregnancy when admitted to the hospital. Her family and personal history had no bearing on the case. She had a greatly distended abdomen which measured 55 inches at the level of the umbilicus and there was a slight cyanosis. One day after admission marked edema of the lower limbs set in and the tentative diagnosis of polyhydramnios having been made the membranes were punctured; only a small amount of amniotic fluid escaped. A Champetier de Ribes bag was introduced and the vagina packed with gauze. A small child was expelled spontaneously. The abdomen was still distended with fluid and as the patient seemed distressed the abdomen was tapped with a trocar and two gallons of fluid withdrawn. It was clear, yellow, and had a spe-

cific gravity of 1016. The circumference at the umbilicus was 36.5 inches. Dr. Jacobson first saw the patient October 2, 1910, eleven days after her admission, and found unmistakable carcinoma of the left ovary which filled the left abdominal quadrant. Four days later he performed a laparotomy. The carcinomatous cyst was moderately adherent to the anterior abdominal wall, small intestine, and, by one band, to the liver. The diagnosis was confirmed by Dr. Eli Moschcowitz, who pronounced the growth a papillary adenocarcinoma. The patient made a good recovery, the convalescence being temporarily interrupted by a rise of temperature and pelvic effusion about nine days later. This condition was cleared up by an incision in the posterior cul-de-sac. An examination on February 27, 1913, showed her to be pregnant three months, but there was no sign of any recurrence and she looked and felt perfectly well. In view of the danger of malignant degeneration of ovarian tumors it ought to be the practice to remove all ovarian tumors at the earliest possible moment.

Septate Uterus Causing Fatal Puerperal Septicemia.—Dr. Sidney D. Jacobson made this report. This malformation of the uterus, which caused the woman her life, was a variety of arrested development, caused by a failure of proper coalescence of the Müellerian ducts with consequent absence of absorption of the septum between the two halves of the fetal uterus. The patient was thirty-four years old and a primipara. During the first week in June, 1907, she went into labor at term and was delivered in her home by the aid of median forceps. Within a few hours her temperature rose to 104 F. and she began to show all the typical signs of puerperal sepsis. Dr. Jacobson was called to see her on the third day after delivery and found her with the symptoms of severe pelvic peritonitis. The interior of the uterus contained a distinct partition running from before backwards and extending almost to the cervix. This partition divided the uterine cavity into two equally sized chambers, one of which was quite empty and the other filled almost entirely with a soft and friable mass of bad odor. This was evidently the cause of her sepsis and the pultaceous mass in one chamber of her bilocular uterus, a false decidua which had not been expelled and had in some way become infected. He advised immediate hysterectomy, but the husband declined and finally agreed to a "cleaning" of the uterus. The uterus was carefully curetted and a considerable quantity of mushy and malodorous material removed. The organ was irrigated with a 50 per cent. solution of alcohol. She improved somewhat but still presented the picture of profound infection. On June 11, 1907, she was removed to the hospital and a hysterectomy performed as a last resort, hoping to give her a fighting chance for recovery. She died on the following day of pulmonary embolus. The specimen of the uterus was shown; it was a large subinvoluted organ cut longitudinally and showed the septum beautifully. The specimen was presented to show the fact that a malformed uterus might become a fatal complication in labor.

Unilateral Fused Kidney with X-Ray Illustrations.—Dr. Arthur Stein reported the case of a woman, thirty-two years old, whose previous history was negative. She was married but had no children. Her menses were not accompanied by pain until five or six years ago; since then the pain had increased in severity. She was told that she had a uterine tumor as well as a tumor on the upper right side of the abdomen which should be removed. All the organs were normal except on the right side of the abdomen where there was a rather hard tumor, larger than the fist, slightly movable, extending to near the median line and disappearing toward the right renal region. The examination was not painful. The left kidney could not be palpated. There was a retroflexion of the uterus and at the posterior wall there were several small myomata which altogether were no larger than an orange. A diagnosis was made of multiple myoma and there was a suspicion of congenital horseshoe or unilateral fused kidney. The abdomen was opened, the myomata removed, and the uterus was found to be fixed to the anterior abdominal wall. In order to determine the precise nature of the right abdominal tumor, the posterior peritoneum was incised at the level of the tumor, and it was immediately seen that they had to deal with renal tissue. The small peritoneal incision was then closed. The left side was carefully examined in search of a kidney but none could be found, and the abdominal wound was then closed. Several weeks after the patient had left the hospital several *x*-ray pictures showed that both of the catheters inserted into the ureters deviated to the right and both were arrested at the same level. The injection of 30 per cent. of calargol into the renal pelvis demonstrated the fact that there were two renal pelves which were distinctly visible in the illustration. They were thus forced to the conclusion that they had to deal with a congenital fusion of two kidneys with seperate pelves and separate uterus, the openings of which were both at normal positions in the bladder. The typical horse-shoe kidney was found about once in 1,000 autopsies, the unilateral fused kidney much more rarely. This case was the only one reported in which a unilateral kidney was found to be absolutely healthy, the patient applying for treatment chiefly on account of uterine troubles.

Extirpation of the Kidney for Multiple Fistulæ.—Dr. Arthur Stein reported the case of a patient, thirty-nine years old, who had been operated upon for bilateral pyosalpinx on May 5, 1911. The pyosalpinx was firmly adherent to the omentum on both sides, and there was an extensive general adhesion of the genitals to the intestines and a fresh peritonitis. In the attempt to remove the tube it burst and a large quantity of pus was evacuated into the peritoneal cavity. While attempting to remove the left pyosalpinx the tissues were found to be so brittle that hemorrhage could not be arrested and a total extirpation was carried out. The drainage of the abdominal wound was upward and toward the vagina. About eight days after the operation urine was found escaping through the abdominal incision; after the usual treatment this fistula closed in about two months. About three weeks after the formation of this fistula, a vaginal fistula of the left ureter developed. The patient was discharged on July 4 with the abdominal wound closed but with the uretero-vaginal fistula still patent. She was directed to return in a few months to have it closed; she returned on August 31 in a rather emaciated and debilitated condition and stated that she had lost eighty pounds since the former operation. She complained of continuous pain in the left inferior part of the abdomen and had had chills during the week prior to her return. There was a pronounced feeling of pain along the left uterer, especially in its lower part. The vagina contained urine, but otherwise the wound was found in a normal postoperative condition. The bladder had a capacity of about 300 c.c. The walls of the bladder were normal. The aperture of the left ureter was somewhat distorted and no urine was seen to escape from it. In introducing the catheter into the left ureter no difficulty was experienced but an obstacle was encountered about one inch above the aperture making it impossible to insert the catheter any further. The function of the right kidney and ureter was normal. At the vaginal examination a narrow opening was found in the left fornix through which clear urine flowed very copiously. This opening was located about 3 cm. above the left fornix. Judging from an examination of the urine from the left kidney, it did not seem to be inflamed. On September 15 an incision was made between the old scar and the anterior superior spine and there were found extensive old adhesions, especially between the bladder and the anterior abdominal wall. The ureter was distended to the thickness of the little finger and was very edematous. It was dissected free in its whole length down to the fistula where it was ligated and cut off, the proximal end being implanted into the bladder with two flaps in the usual way. The wall of the bladder was fixed to the external wall of the ureter with seven or eight sutures. In order to secure abundant nutrition for the ureter, as much mesenterial fat as possible and adjacent intestine was sutured above it. The bladder was filled in order to demonstrate any possible leakage, but the place of implantation was quite impermeable. On the sixth day after the operation there was a gradual return of the urinary dribbling from the vagina and a few days later from the abdominal wound. The bladder was perfectly intact and consequently they had to deal with simultaneous fistulæ between the ureter and vagina and between the ureter and the abdominal wall. The patient recovered but none of the fistulæ closed. A radical operation for the removal of the fistulæ was decided upon and two courses were considered—first, an attempt at implanting the ureter into the colon, and, secondly, the total removal of the kidney. The latter operation was chosen after it had been established that the right kidney was in absolutely normal working order. On October 11 the left kidney was extirpated. The patient passed through a normal convalesence, the right kidney voiding clear, normal urine in quantities varying between 1,000 and 2,000 c.c. From the laboratory came the report that there was present a chronic interstitial nephritis and parenchymatous degeneration, together with a chronic pyelitis.

Hernia of the Uterus and Both Adnexa, with Report of a Case.—Dr Lillian K. P. Farrar read this paper. She reviewed the instances of this condition reported in the literature from 97 A. D., when, according to Peyrilke, Soranus of Ephysia stated that he had seen with his own eyes "a loop of small intestine descend in the inguinal canal preceded by one ovary," owing, as he said, "to the relaxation of the broad ligaments which retained and enveloped it and together with which the suspensory had also escaped." This case was of interest as a description of what might be called the first stage of the hernia of the genitalia. The writer reviewed the cases reported in the literature under three stages, (1) hernia of the ovary, (2) hernia of one adnexa and the uterus, and (3) hernia of both adnexa and the uterus. The case which the writer presented was that of a patient, 32 years of age, who had had five children, the eldest seven and one-half years and the youngest nine months. The first four labors were easy. During the second and third months of the second pregnancy the patient noticed a mass in the left inguinal region, which was tender on pressure and reducible when she was in the recumbent position. The mass appeared again in the third pregnancy but was absent during and after the fourth. In the fifth pregnancy it appeared at about the third month and was much larger and more painful than before. On rising on the seventh day after labor she noticed the mass, which remained reducible for about four weeks and then was irreducible for five weeks. On examination a left inguinal hernia was found which was irreducible and contained a solid body, broader below than above, firm in consistency, and somewhat tender on palpation. Two smaller growths were palpable below this organ and two others on a higher plane in the hernial sac. On bimanual examination, the cervix which was high in the vagina was found drawn to the left, and continuous with the tumor in the hernial sac. A diagnosis of hernia of the uterus and both adnexa was therefore agreed upon. At operation the uterus, two ovaries, two Fallopian tubes, and two broad ligaments were found in the canal of Nuck. The uterus was turned to the right with the left adnexa anterior to the uterus and the right posterior. Both the adnexa and the uterus were normal. The hernial ring measured two inches in circumference and the tissues of the canal were very much softened. The round ligament was three of four times its normal size. The uterus and adnexa were easily returned to the abdominal cavity and the wound closed by the Bassini method. The patient had had one child since with a labor of five and one-half hours duration and there had been no return of the hernia. At present the uterus was in good position and only slightly to the right of the axis of the pelvis. Dr. Farrar reviewed the theories that had been advanced as to the cause of hernia of the uterus and the conditions necessary for the formation of a hernia. She then discussed the diagnosis and operative treatment and concluded as follows: 1. There were only two varieties of hernia of the uterus and both adnexa, namely, inguinal hernia and femoral hernia. The inguinal variety was by far the most common and the only one in which a hernia of a pregnant uterus had occurred. 2. In inguinal hernia of the uterus, there were two types, (a) congenital, which was the most frequent, and (b) the acquired, which was infrequent if it occurred at all. 3. Hernia of the uterus occurred in infancy, usually associated with malformation of the genitalia, or in adult life after numerous pregnancies. If it occurred between infancy and adult life, there were usually hermaphroditic malformations. 4. Hernia of the uterus was always secondary to hernia of one adnexa, but a hydatid of Morgagni, or a broad ligament, might precede the ovary into the hernial ring. 5. The diagnosis rested on symptoms which were connected with the pelvic organs and not with the intestine. The diagnosis was usually based on the signs of pregnancy occurring in the patient together with the changes occurring in the hernial tumor. Hernia of the non-pregnant uterus could be diagnosed only by bimanual examination. 6. The treatment was always operative, either on the pregnant uterus for the relief of the immediate condition, or on the non-pregnant uterus to prevent degenerative changes in the organs or to avoid the danger of pregnancy in the hernial sac. 7. The causes were probably not single, but several associated. (a) Adhesive peritonitis in intrauterine life produced malformations and displacements of the genital organs which rendered them more liable to hernia. (b) The processus vaginalis peritonei made an opening favorable for hernia. (c) In the majority of cases occurring in infancy and childhood it was probably intraabdominal pressure that was the immediate cause of the hernia. (d) In cases occurring in adults, multiple pregnancies, subinvolution of the uterus and adnexa, or a previous inguinal hernia of the intestine were the secondary causes favoring its formation. (e) In some cases it was apparently the round ligament as Eisenhart and Winckel had stated that drew the ovary as the gubernaculum of Hunter drew the intestine into the inguinal canal. (f) In certain other cases it seemed probable that the broad ligament might first become adherent to the internal ring or to the processus vaginalis peritonei and form a reduplicature, and so draw the ovary in by a mechanism analogous to the gliding hernia of the large bowel. (g) If the intestine or omentum to which an ovary was adherent was in the hernial sac it seemed only logical to consider that the ovary which had made its way into the inguinal canal, in a manner analogous to the testicle, had in the same manner as the testicle dragged a loop of bowel after it into the hernial sac. The ovary being, therefore, the origin of the hernia and not the intestine as Keustner and Eisenhart had stated.

Dr. William B. Coley believed Dr. Farrar's paper to be the most interesting and scholarly paper on hernia of the uterus that had yet been written. He said he wished to report two cases that came under his personal observation. Hernia of the uterus alone, without the tube or ovary, was an extremely rare condition. In nearly 4,000 operations at the Hospital for Ruptured and Crippled, of which about 700 were performed upon the female, the ovary had been found alone in 4 cases, the tube alone in 1 case, the tube and ovary in 7 cases, and the uterus and tube in 2 cases. Personally, Dr. Coley had operated upon 1 case of hernia of the ovary alone, 1 of the tube alone, 5 cases in which the sac contained the tube and ovary, and 2 cases of hernia of the uterus.

Case I.—This patient was four and a half years old and was operated upon for double oblique inguinal hernia of three years' duration, a truss having been worn for two years. Operation was first performed on the right side; the sac was found to contain a broken tube and one horn of a bicornate uterus. In the left hernial sac was found a large and more completely developed horn of the uterus with a well developed tube, and a large ovary which contained a few small cysts. The hernia on the left side resembled in type, a sliding hernia of the sigmoid or cecum, the uterus being attached to the posterior wall of the sac low down, making a high closure of the sac difficult. The peritoneum was separated from the surrounding tissue, the lower portion of the sac was cut off, and the upper portion pushed down into the cavity. An uneventful recovery followed.

Case II.—This patient was ten years old and had a hernia the size of a walnut, partly reducible. She had worn a truss since infancy. The operation disclosed a large sac which contained the left tube and ovary and a large part of the uterus apparently normal in size. The left tube was adherent to the posterior wall of the sac. Bassini's operation was performed and was followed by an uneventful recovery.

Hilgenreiner up to 1905 was able to find reported but 37 cases of hernia of the uterus and his statistics showed it to have occurred most frequently in middle aged women who had borne children. In nearly one-half of the cases reported the trouble was associated with defects and malformations of the genital organs. The diagnosis was seldom made before operation except in cases complicated with pregnancy. Dr. Coley did not believe it was possible to make a diagnosis in children. As regards the etiology of hernia of the uterus, Dr. Coley believed the chief cause in children to be an abnormal mobility, or malformation of the uterus associated with a congenital sac and an abnormally large opening in the canal.

Dr. Sidney D. Jacobson presented certain facts in embryology to show that it was not difficult to understand the malformations of the uterus due to faulty coalescence of the Muellerian ducts. Their cause was not determined yet. It had also been noticed that women suffering from double uterus had strikingly broad hips. He regretted that he could not agree with Dr. Farrar that these malformations of the uterus were always due to bands caused by a fetal peritonitis.

Tuberculous Disease of the Middle Ear.—G. N. Biggs states that facial paralysis in children associated with aural discharge and unaccompanied by any symptoms of labyrinthine or intracranial disease is pathognomonic of tuberculosis of the middle ear.—*British Journal of Diseases of Children.*

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Idaho State Board of Medical Examiners.

October, 1912.

ANATOMY.

1. Give the origin, insertion, and nerve supply of the obliquus externus abdominis.
2. Describe the relations between the median nerve, brachial, and ulnar arteries.
3. Describe the portal circulation.
4. Describe the hip joint.
5. Describe briefly the inferior vena cava and its tributaries.

HISTOLOGY.

1. Describe the structure of the stomach.
2. Classify the different tissues and describe briefly where found.
3. Describe the structure of the skin.
4. Describe the structure of a uriniferous tubule.
5. What is the distinguishing difference between an artery and a vein?

PHYSIOLOGY.

1. What four chemical elements enter most largely into the construction of animal bodies.
2. Describe the portal circulation.
3. Discuss the function or functions of the spleen.
4. Name the types of muscle tissue and outline the parts played by each.
5. Describe the gastric juice.
6. Name the active principle of the saliva, and state the time required for the splitting up of starch cells in the mouth.
7. What effect has paralysis of the radiating fibers of the iris on the eye?
8. Is the sphincter vesicæ a voluntary muscle? (*a*) how stimulated (*b*) how inhibited?
9. Define the following terms concerning the phenomena of muscle action, summation, tetanus, contraction clonus, clonusmus, tonus, and rigor.
10. Which nerve supplies the upper incisors and canine teeth?

CHEMISTRY AND TOXICOLOGY.

1. Give chemical formula for (*a*) phenol; (*b*) lunar caustic; (*c*) mercurous chloride; (*d*) mercuric chloride; (*e*) methyl alcohol.
2. How are the two chief bile pigments formed?
3. What is the action of KHO when taken internally and what antidotes should be used?
4. Give method of disinfection in detail (*a*) with sulphur; (*b*) with formaldehyde. Which is the more efficient and why?
5. What is the cause of lactic acid in the stomach and how can it be separated from hydrochloric acid?
6. Give the post mortem findings in a suspected case of electrocution.
7. Give treatment, symptoms, and post mortem findings of oxalic acid poisoning.
8. Define the terms (*a*) rape; (*b*) rigor mortis; (*c*) hermaphrodite; (*d*) infanticide; (*e*) wound.
9. What is the general treatment of all cases of acute poisoning?
10. Name five neurotic poisons with symptoms and treatment for same.

ANSWERS.

ANATOMY.

1. The *external oblique muscle* of the abdomen *arises* from the eight lower ribs; is *inserted* into the anterior half of the outer lip of the crest of the ilium, and Poupart's ligament; *nerve supply*, the lower intercostal nerves, the iliohypogastric and ilioinguinal.

2. The *median nerve* lies at first on the outer side of the axillary artery, then crosses it, then lies on the inner side of the artery; it is at first on the inner side of the brachial artery, then crosses it, and then passes to the middle of the forearm and ceases to be in intimate relation with the artery.

3. *Portal circulation:* "The hepatic artery and the portal vein convey blood to the liver. The artery carries arterial blood, and the vein food-laden venous blood from the walls of the alimentary canal, and from the spleen and pancreas. Both vessels enter the liver at the transverse fissure, and they ramify in its interior, breaking up into small terminal branches which run between the lobules and send fine capillary branches into their substance; from these latter branches the blood passes into the capillary tributaries of the intralobular veins, thence to the sublobular veins, and from the sublobular veins to the hepatic veins which terminate on the posterior surface of the liver in the inferior vena cava."—(Bain's *Medical Practice.*)

4. The *hip-joint* is an enarthrodial joint, formed by the head of the femur and the acetabulum. The articular surfaces are covered with cartilage. Near the center of the head of the femur is attached the ligamentum teres. The *ligaments* are: (1) The capsular, which embraces the margin of the acetabulum above, and the neck of the femur below. (2) The ileofemoral or Y ligament, which passes obliquely across the front of the joint, and is attached above to the anterior inferior spine of the ileum, and below to the anterior intertrochanteric line. (3) The ligamentum teres. (4) The cotyloid ligament, which deepens the acetabulum, and bridges over the cotyloid notch, being there called (5) the transverse ligament. The joint has a very extensive synovial membrane. It is capable of the following movements: Flexion, extension, abduction, adduction, circumduction, and rotation.

5. The *inferior vena cava* is formed by the junction of the two common iliac veins in front and a little to the right side of the fourth or fifth lumbar vertebra. It passes upon the right side of the aorta, to the posterior surface of the liver, where it receives the hepatic veins; it passes through the diaphragm, perforates the pericardium, and enters the lower and back part of the right auricle. The *tributaries* are: Lumbar, right spermatic, renal, suprarenal, phrenic, and hepatic veins.

HISTOLOGY.

1. "The *wall of the stomach* consists of four coats, which, enumerated from without in, are: serous, muscular, areolar, or submucous, and mucous membrane. The *serous coat* is a layer which is derived from the peritoneum. It is deficient only along the lines of the lesser and greater curvatures. The *muscular coat* consists of three layers of plain muscular fibers. Of these the bundles of the outer layer run longitudinally, those of the middle layer circularly, and those of the inner layer obliquely. The longitudinal and circular bundles become thicker and stronger toward the pylorus, at which they pass into the corresponding layers of the small intestine; at the pylorus itself the circular layer is greatly thickened to form the sphincter muscle. The oblique fibers are only present in the left or cardiac part of the stomach. The *areolar or submucous* coat is a layer of areolar tissue, which serves to unite the mucous membrane loosely to the muscular coat; in it ramify the larger branches of the blood vessels and lymphatics. The *mucous membrane* is a soft thick layer, generally somewhat corrugated in the empty condition of the organ. Its inner surface is covered by long columnar epithelium cells, all of which secrete mucous. They are prolonged into the ducts of the glands, but when these divide to form the tubules the cells become shorter (cubical). The thickness of the mucous membrane is due to the fact that it is largely made up of long tubular glands, which open upon the inner surface. Between the glands the mucous membrane is formed of retiform with some lymphoid tissue. Externally it is bounded by the muscularis mucosæ, which consists of an external longitudinal and an inner circular layer of plain muscular fibers."—(Schäfer's *Essentials of Histology.*)

2. The *different tissues* are: Epithelial, connective, muscular, and nervous. *Epithelium* is found lining the vascular and lymph systems, in glands, in the ducts and cavities of the body, on the skin, etc. *Connective tissue* is found in tendons, ligaments, fasciæ, aponeuroses, skin, blood-vessels, lungs, intestines, etc. *Muscular tissue* is found in the voluntary and involuntary muscles and in the heart. *Nervous tissues* are found in the brain, spinal cord, and nerves.

3. "The skin consists of: (1) Epidermis or cuticle. (2) Dermis, corium, or cutis vera. (3) Sweat glands, nails, hair, and sebaceous glands.

"The *epidermis* forms a protective covering over the whole surface of the body. It is moulded over the surface of the corium, covering the ridges, the depressions, and the papillæ. It is made up of three principal layers: (*a*) the horny layer, or *Stratum corneum*, is the most superficial, and consists of layers of flattened cells, which are dry and horny without any nucleus; (*b*) the *Stratum lucidum*, composed of several layers of nucleated cells, which are more or less indistinct, and in section appear as an almost homogeneous layer; (*c*) the *Rete mucosum* or Malpighian layer contains, in its upper part, layers of

'prickle' cells, and its inferior layer consists of a single stratum of columnar cells. Pigment is principally found in the lowest layer.

"The *dermis*, or true skin, is made up of an interlacing network of connective tissue, formed of white fibrous tissue, yellow elastic tissue, corpuscles, vessels, and nerves. In some parts of the body, as in the skin of the scrotum, perineum, penis, the cutis vera contains unstriated muscular fibers. There are also small muscular fibers in connection with the hair follicles. Beneath the skin the subcutaneous tissues contain abundant adipose tissue. Numerous fine ridges are seen on the surface of the skin of the palm of the hand, and sole of the foot. The ridges are caused by rows of little elevations of the cutis vera, termed papillæ. These little eminences are more or less conical, or sometimes club-shaped; they may be compound, and contain a capillary loop, nerve, and touch-corpuscle; they project into the epidermis, and by raising it up, as it were, form a ridge on the surface of the skin. They serve to increase the sensitiveness of the part, lodging a touch-corpuscle in a favorable position for receiving sensations of touch."—(Ashby's *Notes on Physiology.*)

4. "Each *uriniferous tubule* commences in a globular capsule—Bowman's capsule—which surrounds a glomerulus of blood-vessels, the whole forming a Malpighian body. The tubules are at first convoluted, then become narrowed, and form loops of Henle, which dip down into the base of the pyramid; these loop tubules return into the cortex, and again become convoluted. The second convoluted portion ends in a short, narrow tubule. Several of these unite to form a straight tube, which they usually join at nearly a right angle; the straight tubes unite in pairs and form the greater part of the pyramid. The straight tubules open into little pits at the apex of a pyramid, by which the urine is discharged into one of the calices. The urinary tubules consist of a fine membrane lined with epithelium. The epithelium is cubical in the convoluted portions, somewhat flattened in the loop tubules, and cubical or columnar in the straight tubes of the pyramid. Bowman's capsule is lined by a layer of flattened epithelial cells, which is reflected over the vessels of the Malpighian tuft."—(*Aids to Physiology.*)

5. *Differences between arteries and veins:*

ARTERIES.	VEINS.
Generally carry arterial blood.	Generally carry venous blood.
Carry blood from the heart.	Carry blood to the heart.
Do not collapse when cut.	Collapse when severed.
Are found contracted and empty after death.	Are not found empty after death.
The middle coat is the thickest.	The external coat is the thickest.
Do not have valves.	The medium-sized veins have valves.

PHYSIOLOGY.

1. Carbon, hydrogen, oxygen, and nitrogen.

2. See above. ANATOMY, 3.

3. The *function of the spleen:* The following theories have been held: (1) It is a source of production of the white blood corpuscles; (2) it is a source of production of the red blood corpuscles during fetal life; (3) it is a place where the red blood corpuscles are destroyed; (4) uric acid is produced in the spleen; (5) an enzyme is produced in the spleen and is carried by the blood to the pancreas, where it converts the trypsinogen into trypsin.

4. The types of muscle tissue are voluntary and involuntary; also cardiac. The *voluntary* muscles are striped, are more or less under the control of the will, do not contract rhythmically, do not evince peristalsis, and the nerves to them end as "end-plates." The *involuntary* muscles are unstriped, are not under the control of the will, contract rhythmically, show peristalsis, and the nerves to them end as a "plexus." The cardiac muscle is the heart.

5. The *gastric juice* is a fluid, of acid reaction, specific gravity of about 1001 to 1010, and is composed of water and solids, the latter being about one-half of one per cent. About 10 or 12 pints are secreted daily. It contains pepsin, hydrochloric acid, mucin, salts, a curdling ferment, and water. The pepsin converts the proteids into proteoses and peptones.

6. The active principle of the saliva is called *ptyalin.* The time required for the ptyalin to split up the starch cells depends upon the starch. If the starch is boiled, it may be accomplished in a few minutes; unboiled starch may require even a few hours.

7. Paralysis of the radiating fibers of the iris causes contraction of the pupils.

8. There is no *voluntary muscle* by the name of *sphincter vesicæ.* "When the urine has passed into the bladder, it is there retained by the sphincter vesicæ muscle, kept in a state of chronic contraction by the action of a nerve center in the lumbar region of the spinal cord. This center can be inhibited and the sphincter relaxed, either reflexly, by impressions coming through sensory nerves from the mucous membrane of the bladder, or directly, by a voluntary impulse descending the spinal cord. When the desire to urinate is experienced impressions made upon the vesical sensory nerves are carried to the centers governing the sphincter and detrusor urinæ muscles and to the brain. If now the act of urination is to take place, a voluntary impulse originating in the brain passes down the spinal cord and still further inhibits the sphincter vesicæ center, with the effect of relaxing the muscle and of stimulating the center governing the detrusor muscle, with the effect of contracting the muscle and expelling the urine. If the act is to be suppressed, voluntary impulses inhibit the detrusor center and possibly stimulate the sphincter center."—(Brubaker's *Compend of Physiology.*)

9. *Summation* of stimuli is the muscular or mental effect produced by the frequent application of slight stimuli, one of which alone would be without evident response.

Tetanus is a tonic muscular contraction, especially induced by an electrical current.

Clonus is a form of convulsion marked by contractions and relaxations of a muscle, occurring in rapid succession.

Clonismus is a long continued state of clonic spasm.

Tonus is the state of normal elastic tension.

Rigor is the hardening and stiffening of the muscular tissues. (From Stedman's *Medical Dictionary*).

10. The upper incisors and canine teeth are supplied by the anterior superior dental branch of the superior maxillary division of the trigeminal (fifth cranial) nerve.

CHEMISTRY AND TOXICOLOGY.

1. Phenol. C_6H_5OH. Lunar caustic, $AgNO_3$. Mercurous chloride, Hg_2Cl_2. Mercuric chloride, $HgCl_2$. Methyl alcohol, CH_3OH.

2. Bile pigments are formed in the liver from the coloring matter of the blood, by the disintegration of the red corpuscles.

3. KHO, taken internally, is a corrosive, and distintegrates the tissues; it has a caustic action, may perforate the stomach, or cause thickening of the stomach walls with closure of one or both of the orifices of the stomach. The antidote is dilute acid or vinegar.

4. "*Sulphur dioxide* is a powerful germicide and a good surface disinfectant; the disadvantages of sulphur dioxide for disinfection are (1) that it is not very penetrating, (2) that it does not destroy spore-bearing bacteria, (3) that it damages textile fabrics, (4) that it bleaches vegetable colors, and (5) that it injures and tarnishes metals. It is also very poisonous to those handling it, causes injury to the mucous membranes of the eyes, and nose, and throat, and leaves a very disagreeable odor, clinging to materials for a very long time. Several methods of sulphur disinfection are employed: The pot, candle, or liquid form; also by means of furnace. About five pounds of sulphur are used for every 1,000 cubic feet of space to be disinfected. Moisture and heat increase the penetrating qualities of the gas and the value of disinfection. An exposure of twenty-four hours is necessary for thorough disinfection, and as the gas is very diffusible precautions must be taken effectively to close all windows, doors, and all cracks, crevices, and other apertures found in the room. Sulphur disinfection is preferable wherever surface disinfection is needed and where there are few articles which would be deteriorated by it, also wherever insecticide action is demanded.

"*Formaldehyde* gas has greatly superseded sulphur dioxide as a disinfectant. Its main value is that, while it is a good germicide, it does not destroy fabrics and injure objects as the latter, and also it is nontoxic. Formaldehyde is also but a surface disinfectant, its penetrating qualities not being very great. Bacteria are killed by formaldehyde immediately on direct exposure, and spores within an hour. It kills dried organisms as well as those in a moist state. Formaldehyde is not an insecticide. For domestic disinfection formaldehyde is generated by spraying liquid formalin (which contains 40 per cent. of the gas), or by heating paraform pastils or powder, also by means of generators or lamps. Other methods of evolving formaldehyde in disinfection which are used in large house and hospital disinfections are by means of large generators or lamps, or in specially constructed autoclaves under pressure, or in retorts without pressure."—(Price's *Hygiene and Public Health.*)

5. Lactic acid is formed in the stomach during the digestion of carbohydrates.

Test for lactic acid: Put three drops of concentrated solution of phenol and three drops of an aqueous solution of ferric chloride in a little water; to this add the solution to be tested; if lactic acid is present the blue color turns to canary yellow.

Test for hydrochloric acid: Put a few drops of the filtered gastric juice in a porcelain dish, and add a drop of 0.5 alcoholic solution of dimethylamidoazobenzol; a cherry red color indicates the presence of hydrochloric acid.

6. In *death from an electric current,* rigor mortis is usually marked, the heart is flaccid, the large veins, the brain, and abdominal viscera are congested, the left heart is empty, the right heart is full of blood, the blood contains oxyhemoglobin and reduced hemoglobin.

7. Oxalic acid poisoning. *Symptoms:* Pain, vomiting, nervous symptoms such as twitching, coma, prostration, cardiac depression, cramps, delirium, convulsions; symptoms are very variable. *Treatment:* Magnesia in solution should be given in large doses; this should be followed by an emetic; the depression and prostration may then require treatment.

Post-mortem findings: "No matter what the size and concentration of the dose may be, there is always a greater or less amount of bleaching and softening of the mucous membranes; they may be covered with a soft brownish coat representing the discharges from the stomach. The stomach as a rule contains a dark-brown, more or less gelatinous fluid. The mucous membrane of the stomach will usually be pale and softened, in some cases presenting no signs of inflammation. It will usually be easily separated from the walls of the stomach and will appear as if boiled. The intestines are usually congested if death has been delayed for even a few hours. The lungs and brain have been found congested. The heart is usually flabby, and may be either empty or full. The blood is dark-colored and fluid. The kidneys, where life has been prolonged, may exhibit a peculiar white line in their cortical areas, representing an accumulation of calcium oxalate." (Dwight's *Toxicology.*)

8. *Rape* is carnal knowledge of a woman without her conscious permission, or with such permission extorted by fraud or force.

Rigor mortis is the stiffening of the muscles of the body observed after death.

Hermaphrodite is an individual who possesses both ovaries and testicles.

Infanticide is the destruction of life in a newly born child. *Wound* is a solution in continuity of any of the tissues of the body.

9. *General principles of treatment:* "(1) Lose no time. (2) Use the best remedy obtainable at once. (3) Get rid of the poison. (4) Stop its action. (5) Remedy the mischief already done. (6) Fight against the tendency to death (Tanner). In the treatment of poisoning, whether by mineral or vegetable substances, if the poison is known the first indication is to administer the proper chemical antidote, so as to render it harmless or comparatively so. Next, the stomach should be emptied and washed out, lest the newly-formed compound be absorbed after a time, also to remove any poison which may have escaped the action of the antidote. Next, the appropriate antagonist should be administered, to counteract the effects of such portion of the poison as may have been absorbed. Lastly, such antagonistic measures should be employed as may sustain the action of any organic function showing signs of failure. In most cases of alkaloidal poisoning absorption has proceeded so far before professional assistance is obtained that antidotes are of no value, hence reliance can be placd only upon the physiological antagonist and such supporting measures as will tend to maintain vitality until the poison can be eliminated by the natural channels." (Potter's *Materia Medica,* etc.)

10. *Five neurotic poisons:* Morphine, cocaine, strychnine, atropine, and aconite.

Morphine. *Symptoms:* "At first there is usually a period of excitation, marked by restlessness, great physical activity, loquacity, and hallucinations. The patient then becomes weary, dull, and drowsy; he yields to the desire for sleep, from which at first he may be roused. The lips are livid, the face pale, the pupils contracted, and the surface bathed in perspiration. The condition of somnolence rapidly passes into narcosis. The patient cannot be roused, and lies motionless and senseless, with completely relaxed muscles. The pulse, at first full and strong, becomes feeble, slow, irregular, and easily compressible; the respiration slow, shallow, stertorous, and accompanied by mucous râles. The patient rapidly becomes comatose, and, in fatal cases, dies in from forty-five minutes to fifty-six hours, usually in from twelve to eighteen hours. In cases of recovery after the stage of narcosis, the pulse and respiration gradually return to the normal, and the condition of coma passes into one of deep sleep, lasting twenty-four to thirty-six hours."

Treatment: "Wash out the stomach with a dilute solution of potassium permanganate, leaving about 500 c.c. in the stomach, and in maintaining the respiration. In the first or second stage the 'ambulatory treatment' should be adopted to prevent, if possible, the establishment of the third stage. If this stage develop, the main reliance is to be placed in maintaining the respiration by artificial methods, until the poison has been eliminated. Strong coffee, or caffeine, by the mouth or rectum, are of benefit. The same cannot be said of atropine. The urine should be drawn by the catheter."

Cocaine: *Symptoms:* Pain and fulness in the head, pulse at first quick but later feeble and slow; extremities cold. The symptoms are not constant.

Treatment consists in the administration of ammonia or coffee; morphine, strychnine, chloroform, and ether have all been suggested; artificial respiration may be necessary. The safest plan is to treat whatever symptoms are present.

Strychnine. *Symptoms:* "A sense of suffocation, thirst, tetanic spasms, usually opisthotonos, sometimes emprosthotonos, occasionally vomiting, contraction of the pupils during the spasms, and death, either by asphyxia during a paroxysm, or by exhaustion during a remission. The symptoms appear in from a few minutes to an hour after taking the poison, usually in less than twenty minutes; and death in from five minutes to six hours, usually within two hours."

Treatment: "The convulsions are to be arrested or mitigated by bringing the patient under the influence of chloral or chloroform as rapidly as possible; the stomach is to be washed out, and the patient is to be kept as quiet as possible." (Witthaus' *Essentials of Chemistry.*)

Atropine. *Symptoms:* "In the first stage, that of delirium, there are dryness of the throat, thirst, difficulty of deglutition and spasms upon swallowing liquids, face at first pale, afterward highly reddened, pulse extremely rapid, eyes prominent, brilliant, with widely-dilated pupils, complete paralysis of accommodation, disturbances of vision, attacks of giddiness and vertigo, with severe headache, followed by delirium, occasionally silent or muttering, but usually violent, noisy, and destructive, accompanied by the most fantastic delusions and hallucinations. Usually the urine is retained, and the body temperature is above the normal. The delirium gradually subsides, and the second stage, that of coma, is established, with slow, stertorous respiration, and gradually failing pulse, until death occurs from respiratory or cardiac paralysis, or sometimes in an attack of syncope during apparent amelioration."

Treatment: Lavage of the stomach; morphine may be given cautiously during the period of violent excitement. Maintain respiration; strong coffee by the mouth or rectum is beneficial. Pilocarpine may be given, in not too large doses, to stimulate the secretion of saliva." (From Witthaus' *Essentials of Chemistry.*)

Aconite. *Symptoms:* "Numbness and tingling, first of the mouth and fauces, later becoming general. There is a sense of dryness and of constriction in the throat. Persistent vomiting usually occurs, but is absent in some cases. There is diminished sensibility, with numbness, great muscular feebleness, giddiness, loss of speech, irregularity and failure of the heart's action."

Treatment: Remove the poison and wash out the stomach with infusion of tea holding charcoal in suspension. Stimulants should be freely administered.

Simple Ulcers of the Jejunum and Ileum.—A. Cade, C. Roubier, and J. F. Martin state that these ulcers are much rarer than those of the duodenum, but are a little more frequent than those of the large intestine. The lesion in most cases in an inflammatory one dependent upon any of the following factors: traumatism, foreign bodies, intoxications, and infections. But circulatory and nervous factors may also be present. Clinically the ulcer is frequently latent and has an insidious course. Usually its first manifestation is a preforation followed by peritonitis. If there are any premonitory symptoms these are apt to be vague intestinal manifestations, such as colic, pain, diarrhea, and less frequently, constipation. Occasionally there may be vomiting. Intestinal hemorrhage is not frequent. According to Ewald the presence of a localized pain regularly associated with the taking of food should arouse the suspicion that an ulcer is present.—*Le Progrès Médical.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

REPORT ON CONDITION OF WOMAN AND CHILD WAGE-EARNERS IN THE UNITED STATES. Vol. XIV; paper; 430 pages. Government Printing Office, Washington.

TEXTBOOK OF DISEASES OF THE NOSE, THROAT AND EAR. By FRANCIS R. PACKARD, M.D. Second edition; illustrated; cloth; price $3.50; 377 pages. J. B. Lippincott Company, Philadelphia and London.

DISEASES OF THE EAR. By PHILIP D. KERRISAN, M.D. Illustrated; cloth; price $5.00; 588 pages. J. B. Lippincott Company, Philadelphia and London.

STUDIES IN CANCER AND ALLIED SUBJECTS. Contributions to the Anatomy and Development of the Salivary Glands in the Mammalia. Conducted under the George Crocker Special Research Fund at Columbia University. Volume IV; cloth; price $5.00 net; 364 pages; illustrated. Columbia University Press, New York.

COPROSTASIS. By Sir JAMES SAWYER. Cloth; 74 pages. Cornish Bros., Birmingham.

BLOOD PRESSURE IN GENERAL PRACTICE. By PERCIVAL NICHOLSON, M.D. Illustrated; price $1.50; cloth; 157 pages. J. B. Lippincott Company, Philadelphia and London.

REPORT OF THE COMMISSIONER OF EDUCATION FOR THE YEAR ENDED JUNE 30, 1912. Volume XI; cloth; 669 pages. Government Printing Office, Washington.

INTERNATIONAL CLINICS. By leading members of the medical profession throughout the world. Volume XI; twenty-third series, 1913; cloth; price $2.00; illustrated; 312 pages. J. B. Lippincott Company, Philadelphia and London.

SEX: ITS ORIGIN AND DETERMINATION. By THOMAS E. REED, M.D. Cloth; 313 pages; price $3.00; illustrated. Rebman Company, New York.

STERILITY IN THE MALE AND FEMALE. By MAX HUHNER, M.D. Cloth; 276 pages; price $2.00. Rebman Company, New York.

THERAPEUTICS OF THE GASTROINTESTINAL TRACT. By Dr. CARL WEGELE. Illustrated; cloth; 329 pages. Rebman Company, New York.

A COURSE IN NORMAL HISTOLOGY. By RUDOLF KRAUSE. Illustrated; cloth; 86 pages. Part I. Rebman Company, New York.

A COURSE IN NORMAL HISTOLOGY. By RUDOLF KRAUSE and PHILIPP J. R. SCHMAHL, M.D. Part II. Cloth; illustrated; 406 pages. Rebman Company, New York.

OPHTHALMASCOPIC DIAGNOSIS. By Dr. C. ADAM. Illustrated; cloth; 229 pages. Rebman Company, New York.

GENERAL MEDICINE. Volume I. The Practical Medicine Series. Edited by FRANK BILLINGS, M.S., M.D., and J. H. SALISBURY, A.M., M.D. Series 1913. Cloth; price $1.50; illustrated; 404 pages. The Year Book Publishers, Chicago.

GENERAL SURGERY. Volume XI. The Practical Medicine Series. Edited by JOHN B. MURPHY, A.M., M.D., LL.D. Series 1913. Cloth; price $2.00; illustrated; 632 pages. The Year Book Publishers, Chicago.

BERECHNETE ÄRZTLICHE KOSTVERORDNUNGEN NEBST VOLLSTÄNDIGEM KOCHBUCH FÜR ZUCKERKRANKE. By Dr. Med. HERMANN SCHALL. Cloth; 319 pages; price 5.50 marks. Curt Kabitzfch, Wurzburg.

CLINICAL ELECTROCARDIOGRAPHY. By THOMAS LEWIS, M.D., D.Sc., F.R.C.P. Cloth; illustrated; 120 pages. Shaw & Sons, London.

LES ICTÈRES TOXIQUES ET LEUR TRAITEMENT. By NOËL FIESSINGER. Paper; 174 pages; price 2 francs. A. Maloine, Editeur, Paris.

DISEASES OF THE EYE. By G. E. DE SCHWEINITZ, A.M., M.D. Seventh Edition. Cloth; $5.00 net; 979 pages; illustrated. W. B. Saunders Company, Philadelphia and London.

BLOOD-PRESSURE. By FRANCIS ASHLEY FAUGHT, M.D. Illustrated; cloth; price $3.00 net; 281 pages. W. B. Saunders Company, Philadelphia and London.

GONORRHEA IN WOMEN. By CHARLES C. NORRIS, M.D. 521 pages; illustrated; cloth; $6.00 net. W. B. Saunders Company, Philadelphia and London.

REPORT OF THE COMMISSIONER OF EDUCATION FOR THE YEAR ENDED JUNE 30, 1912. Volume I. Cloth; 647 pages. Government Printing Office, Washington.

CLINICS, DEPARTMENT OF PUBLIC CHARITIES

CALENDAR, AUGUST 1913

MONDAY			
Cumberland St. Hospital (Brooklyn)	Surgery	Dr Walmsey	3:00 P.M.
	Laryngology and Rhinology	Dr. Stewart	4:00 P.M.
	Oral Surgery	Dr Shea	4:30 P.M.
TUESDAYS			
Neurological Hospital	Neurology	Dr Byrne	9:00 A.M.
Cumberland St. Hospital (Brooklyn)	Ophthalmology and Otology	Dr Warner	3:00 P.M.
	Surgery	Dr Iler	3:00 P.M.
Kings County Hospital (Brooklyn)	Surgery	Dr. Bogart	8:30 A.M.
	Genito-urinary Surgery	Dr. Morton	2:00 P.M.
	Genito Urinary Surgery	Dr. Fraser	2:00 P.M.
Coney Island Hospital	Surgery	Drs. Fiske and Bogart	10:30 A.M.
	Surgery	Drs. Murphy and Lack	10:30 A.M.
	Medicine	Drs. Hall and Nash	3:30 P.M.
	Medicine	Drs. Hegeman and Byington.	3:30 P.M.
WEDNESDAYS			
City Hospital	Genito-Urinary Surgery	Dr Greene	2:00 P.M.
	Obstetrics	Dr Dorman	2:30 P.M.
Neurological Hospital	Neurology	Dr. Maloney.	10:00 A.M.
Cumberland St. Hospital (Brooklyn)	Gynecology	Dr Pierson	2:30 P.M.
Kings County Hospital (Brooklyn)	Dermatology	Dr Winfield.	1:00 P.M.
	Orthopedics	Dr. Truslow	9:00 A.M.
	Orthopedics	Dr. Napier	2:00 P.M.
Coney Island Hospital	Pediatrics	Drs. Beck and McQuillan.	3:30 P.M.
	Pediatrics	Drs. Pendleton and Van Wart	3:30 P.M.
THURSDAYS			
City Hospital	Gynecology	Dr. Child	2:00 P.M.
	Dermatology	Dr Gottheil	3:00 P.M.
Cumberland St. Hospital (Brooklyn)	Surgery	Dr. Walmsey.	3:00 P.M.
	Laryngology and Rhinology	Dr. Stewart	4:00 P.M.
Kings County Hospital (Brooklyn)	Surgery	Dr. Bogart	8:30 A.M.
	Otology	Dr. Alderton	1:00 P.M.
	Gynecology	Drs. McEvitt and Mills	10:30 A.M.
	Surgery	Drs. Mayne and Rankin	10:30 A.M.
	Surgery	Drs. Fiske and Bogart.	10:30 A.M.
	Surgery	Drs. Murphy and Lack	3:30 P.M.
FRIDAYS			
City Hospital	Laryngology and Rhinology	Dr. Dougherty	2:30 P.M.
	Obstetrics	Dr. Dorman	2:30 P.M.

All registered physicians, visiting and resident and medical students, are cordially invited to attend these Clinics.

Cards of admission, valid until October 1, 1913, may be obtained at the Academy of Medicine, 17 West 43rd Street, Manhattan, and at the Medical Society of the County of Kings, 1313 Bedford Avenue, Brooklyn, as well as from the Secretaries of the several Medical Colleges.

Leucocyte Inclusions in Surgical Diseases.—A. Naccarone notes that in various surgical diseases inclusion bodies are found in the polymorphonuclear leucocytes. The inclusion bodies described by Döhle are therefore not peculiar to nor pathognomonic of scarlet fever. The absolute number of these inclusions and their predominating variety bear no relationship to the various types of cell present, nor do they vary according to the different stages of the disease. The author regards the inclusion bodies as certain resistant forms of parasites.—*La Riforma Medica.*

The Cerebrospinal Fluid in Simple and in Ophthalmic Migraine.—M. J. A. Sicard states that during an attack of simple migraine the cerebrospinal fluid shows neither lymphocytosis nor hyperalbuminosis and has the normal content in urea and glucose. Occasionally its pressure is increased. On the contrary, during a crisis of ophthalmic migraine, the cerebrospinal fluid may be normal, or it may show a hyperalbuminosis with a lymphocytosis. In the former instance the prognosis is favorable, the ophthalmic migraine being but a "neuro-arthritic" episode. In the latter instance the findings indicate an organic meningocortical reaction of syphilitic or tuberculous origin.—*Gazette des Hopitaux.*

NEWER ASPECTS OF THE TREATMENT OF EPILEPSY.*

By L. PIERCE CLARK, M.D.,

NEW YORK.

The first impression derived from a study of the work done upon epilepsy during the past few years is that no new promising therapeutic drug has been introduced during this period. Furthermore, none of those introduced during the corresponding previous period have proven themselves permanent additions to our therapeutic treasury.

If, however, one applies to this work on the treatment of epilepsy those therapeutic possibilities in which shall be represented all methods of treatment of every description, particularly hygienic, dietetic, physical, and psychic remedies, as well as medicamentous ones, we shall soon be convinced that our knowledge of the treatment of this malady has not stood still and that abundant evidence of progress can be found if properly sought for. One might say that the past decade could be designated as one of painstaking, minute and accurate adjustment of principles already known but often inaptly applied in the past.

The past few years have doubtless seen one innovation of far-reaching importance which is so revolutionary that most conventional reviews of our knowledge of epilepsy of a certain type, more particularly the type without mental stigma or deterioration, into the sphere of the affect psychoneuroses. Our knowledge has come about in two principal ways: first, from prolonged study of institutional cases by men like Bratz of Wuhlgarten, whose studies have been quite independent of results of treatment, and second, by the successful application of Freudian psychanalysis by students of Freud, such as Stekel, Jones, Jung, and others. Naturally, this opens the old vexed question of hysteroepilepsy, but of recent writers only one (Sadger) makes use of the term "hysterical pseudo-epilepsy." The majority, while admitting the fact that some confusion must attend reopening the whole problem of the nature of the disease, especially when applied to individual cases, insist that not only is the epilepsy in question typical in every respect but that all the stigmata of hysteria are absent. There can be no doubt, however, that an epileptic showing no deterioration, no stigma of the epileptic character, should be considered carefully in the light of the above suggestion, especially in view of the fact that ten per cent. of all epileptics show no stigma of their disease and, moreover, never deteriorate. There is also a cumulative body of evidence which indeed goes back some years, that even true epileptics may be subject to affect attacks which may even amount to true status. Any careful observer in this field must have seen not a few cases of this sort. In such psychotherapy may reduce these subjects with frequent attacks to the type which present relatively few attacks. Many different methods of mental treatment have proven the correctness of this view. Even quack methods have made use of this fact. Careful investigations of this whole subject should be illuminating and profitable. When we bear in mind that until very recently the dictum has been generally accepted that in true epilepsy there is no affect element, we can understand the revolutionary character of this teaching. It may be simply stated that some true epilepsies may have an element of affects.

Naturally, supposed cases of genuine epilepsy will require years of observation and control, for a subject apparently cured of seizures which have been more or less frequent may be found to exhibit attacks at long intervals which are quite spontaneous. Thus it may ultimately be shown that the recurrence of attacks in a supposedly cured case of genuine epilepsy may be due to the recurrence of a particular affect. This should be noteworthy in the relapsing cases, which in the absence of the other well known excitants such as dietetic errors and like physical causes are not evident.

At the present time our knowledge of the curability of apparently severe cases of epilepsy by methods of psychanalysis rests upon the carefully related case-histories of Stekel and Moedet. However, psychogenous attacks in genuine epileptics are naturally a broader subject in which a number of us have been studying interestedly (Bratz, Stullmen, Friedman, Dana, Jones, Clark, etc.). In reviewing Stekel's cases one is somewhat puzzled by the discrepancy in referring to his cases in one moment as "typical, genuine epilepsy," and in the next as "pseudo-epilepsy." Much will depend in the future study of this question upon the exact status of this point. I have been impressed that many of his so-called genuine epilepsies would not pass muster by experienced epileptologists. It has seemed to me rather that many of his cases are but neuropaths with psychogenous or pseudo epileptic attacks, and therefore our power over true epilepsy has not really been increased beyond palliation. Stekel shows, however, that his patients had certain attributes inseparable from genuine epilepsy. For instance, one of his subjects had the epileptic temperament while the other had at least undergone an apparent mental deterioration but regained his mental powers.

When we bear in mind that considerable time is usually required for successful psychanalysis and that few men have the knowledge of the technique, patience and opportunities to apply it, one must confess that the great bulk of epileptic cases hardly

*Read before the County Medical Society, St. Louis, Mo., January 11, 1913.

avail themselves of this new view of the disease. Hence the greater significance of this research will be one of diagnosis and not therapeusis. It is, however, a line of study which especially needs to be followed up in the future. Moreover it may be borne in mind that the affect element may be reached by other and newer methods in psychanalysis as elaborated and modified by Jung, where failures of new adaptations in life are made of more moment and the consequent regression into the affects of the earlier life is the important issue. While the technique of psychanalysis is not essentially modified thereby, knowing that some early sexual trauma is no longer the nucleus of the affect state, detailed analysis of such becomes less important and imperative of exact analysis. Then, too, as pointed out by Hoch, the failures in adaptations are not in themselves so very important except to disclose the inherent weakness of the trends in the personality and afford us thereby accurate clues to the particular lines of psychic therapeusis. The application of the newer psychological psychiatry to our subject in hand is worthy of an independent paper, which space forbids even outlining.

There has been introduced into psychiatry and neurology a resource which as far as I know has not yet been thoroughly tested in epilepsy. This is the use of pyretogenic substances to induce high temperatures, the rational basis being the fact that not infrequently typhoid and other continued fevers in the insane have been followed by recovery from the psychosis. Such recoveries are occasionally seen in epilepsy—for example, one which followed an attack of erysipelas, which is sometimes quoted.

Until the discovery of the tuberculin reaction we did not have at our disposal any fever-producing resources suitable for routine use. At a later period "nuclein fever" was discoverd. Both these pyretogenic substances have been used freely in general paralysis and are being tested in other psychoses. in an article on the modern treatment of epileptics, published in 1909, Wahl, a French writer, alludes to attempts to induce fever in the belief that thereby convulsions might be prevented. The idea he treats as an old one, never thoroughly tested. The future may doubtless witness a trial of tuberculin or nuclein.

Has chemotherapy, the great resource of the future, developed any point of contact with the therapy of epilepsy? As far as I know, only in connection with salvarsan. Routine use of Wassermann's reaction seems to have shown beyond doubt that only a very small per cent. of epileptics and idiots show a positive test. Of course when the latter is present it is no guarantee that salvarsan is curative, although naturally antisyphilitic remedies would at once be used in such a case. For several years I have been concerned with a number of epileptics in whom the Wassermann reaction has been positive, and in which a history of early infection was obtained. However, antispecific treatment, including that of salvarsan, seems to have produced no noticeable results in the disease. It must be said that two phases of specific epilepsy must be considered; first, the one in which the epilepsy is little less than a symptom of exudative phase of cerebral syphilis and in which salvarsan and other older antisyphilitic remedies are of greatest avail, and secondly, in which the epilepsy is the remote sequence of degenerative changes induced by syphilis and in which latter condition, comparable in part at least with tabes and paresis, is not modified by any antispecific remedies. The point of practical moment to which I wish to call particular attention here is the relatively small number of the latter class in which by spinal puncture and differential cell count one may determine whether or not the exudative phase of the specific disease is entirely passed. It is precisely in this class of syphilitic epilepsy that the older method of treating such cases by a combination of iodides and bromides must have produced such favorable results. The Brown-Sequard mixture was the remedy most frequently employed.

Since epilepsy has recently been studied from the viewpoint of blood pressure, we may ask pertinently whether epileptic seizures like those of puerperal eclampsia are in any way the result of high arterial tension. This is said by Lallemant and Rodiet to be true of menstrual epilepsy in which the pressure rises until a fit occurs. Alcoholic epilepsy might have a similar mechanism, as also attacks which follow the use of tea and coffee, and Féré produced attacks with pilocarpin. A milk-vegetable diet lowers the pressure and this is also the result, somewhat inconstant, of bromides. Rosenberg's antiepileptic "epileptol" is said to lower the blood pressure dangerously if given in too large doses. Although one frequently sees noted that the arterial tension in epileptics is higher on an average than in controls even when under full regimen (bromides, diet, etc.), pressure of over 200 being often mentioned, I have never seen such cases. In my experience the blood pressure is invariably low, ranging from 70 or 80 to not higher than 140 mm. I believe the regimen for epilepsy and arteriosclerosis being placed upon practically the same plane by Lallemant and Rodiet on account of the similarity of arterial tension can be better justified upon quite other and more rational grounds. The defects in protein metabolism in the epileptic when such foods are taken in excess is well known and above all the defect the epileptic suffers in elimination which is so frequently fostered by a high protein diet and a consequent putrefaction may be considered proven. The general employment of blood pressure instruments furnishes important indications for treatment and prognosis, although I advocate their use on quite the reverse grounds than some other observers. To those who follow the high tensionists in the physical make-up of the epileptic, a note of warning needs to be sounded, inasmuch as any extreme lowering of blood pressure in epilepsy may be pronounced hazardous since prolonged use of bromides may have impaired the heart.

An anaphylactic origin has naturally been attributed to epileptic as well as to eclamptic seizures. In attacks at long intervals we may suppose that the cortical cells have been sensitized to some particular toxin while in frequent and serial attacks the cells have become sensitized to irritation of every sort. If we seek a remedy through this clue we come upon the fact that calcium salts are about the sole resource available, so that the indications agree with those of spasmophilia. The use of calcium in epilepsy is not bearing fruit, and it is claimed that an excess of lime in the blood is as bad as a deficit. Attempts to influence the calcium metabolism through thyroid feeding have proved failures largely owing to the fact that the method of administration is probably a very crude system of introducing such substances into the system as compared with the human economy acting in a physiological manner.

The past few years have witnessed no advances in the organotherapy of epilepsy, and the opinion has become more confirmed that but little is to be expected from this source. The thyroid is used by different men for different purposes. One would employ it only in children who show evidences of arrested development in the hope that they might outgrow the disease. A single author gives thyroid substance because he believes it to be the best antibromic. He combines it with bromides. Others believe it indicated in menstrual epilepsy, but this view seems to be ill founded. The old belief that thyroid substance antagonizes spasmophilia has been exploded by the discovery that only parathyroid substance stands in definite relationship to this condition. In 1908 Bouche, a Belgian writer, called attention to this point and suggested that parathyroid extracts be tested in epilepsy. He claims that in the few cases in which thyroid substance is distinctly antiepileptic the rationale is probably to be sought in the presence of a parathyroid admixture. This suggestion has not been carried out to any extent because of obvious difficulties in getting pure glandular products. Isolated cases of improvement under ovarian extract, adrenalin and hypophysis substance have given rise to a belief that a polyglandular extract would be of benefit. More rational is the view that organotherapy should only be carried out in cases in which the existence of an insufficiency of certain extracts can be positively shown. Claude, who has labored for years in this field, not only studies cases from this viewpoint, but also finds in common with others that small doses suffice in certain individuals. He combines the thyroid and ovarian, and hypophysis and ovarian extracts in suitable cases. However, in no case does he dispense with bromides (a strange, therapeutic irony) during the organotherapy. However, it may be said his treatment is intended only to bring about remote results and not to control convulsions. All my personal efforts in this field have been unproductive permanently. More definite knowledge of the function and uses of the ductless glands on the nervous system is nowhere more impatiently awaited than in epileptology.

There is an entirely different phase of organotherapy in which brain extracts have been used. On account of the readiness with which brain substance is obtainable the resource has been tested on quite a large scale. Eulenburg has used Poehl's "cerebrin" both in tablet form and hypodermically. Poehl was very sanguine in some alleged remarkable results in Russia. Eulenburg's results have been as negative as those obtained by the rest of us using this substance in this country. The matter is here introduced and commented upon largely because a rather new application of the principle was made of it in Italy, where a preparation called "cephalopin" has been used for some years by a number of practitioners less as a specific for epilepsy than for the defective and neuropathic substratum. Trevisanello claimed a radical cure of a very severe epilepsy with organic substratum from injections of this substance. That the brain has an internal secretion in the ordinary sense of the term is, of course, highly questionable, but it is by no means impossible that brain substance when used as food may yield cleavage products which are of special nutritive value in nervous insufficiency. Some authorities make use of glycerophosphates and organic phosphorus from the same viewpoint. The recent remarkable results obtained by Abderhalden in feeding animals with cleavage products alone, and even in replacing organic with inorganic nitrogen to a certain extent shows that the line of demarcation between drugs and foods is becoming progressively more ill-defined. Some cleavage products of ordinary digestion are not utilized by economy; while others are potentially toxic and require detoxicating by the economy. It is impossible to state when a cleavage product ceases to act as mere food, for combustion or to replace waste, and begins to assume the activity of a drug. The future organotherapy of epilepsy may consist in the use of synthetic food containing only such cleavage products as are known to be utilizable fully and free from any possible toxicity.

In regard to serotherapy and autoserotherapy—including the use of puncture fluids—it seems safe to say that no progress has been made in the past few years, and there is no promise of any better results. In regard to vaccinotherapy, a discovery has been made which bears indirectly upon epilepsy. It has been shown that both bromides and iodides distinctly lower the opsonic index to the staphylococcus. This, of course, is only what was to have been expected. Whether in the case of those peculiarly susceptible to bromic acne and other pustular lesions a course of vaccinotherapy and staphylotoxins will be worth while must be left to the judgment of the attending physician. Naturally, one would first have to determine whether despite the continued use of bromides the opsonic index could be influenced favorably by the vaccination. A find of some importance is that arsenic is able to elevate the lowered index and this naturally explains its power in antagonizing the bromides and iodides.

The past few years have brought out nothing in favor of any plan of physical therapy for epilepsy. Indeed, the opinion seems to be generally held that everything under this head is all but contraindicated for this malady. This fact is a great stumbling block; for nearly all chronic affections derive benefit from these measures, as do also healthy subjects. Only when their action is purely sedative do we feel that they are really indicated. Radium as far as we know has not been tested fairly. It may be made to quicken greatly the metabolism, and if the opinion is true that an obese epileptic improves upon any plan which reduces his weight, it should be indicated in such cases. But the same law holds good for thyroid feeding which also intensifies metabolism, yet has not benefited epilepsy in general.

Since a sluggish colon must usually be due to atony, anything which can overcome the latter by physiological means should be a desideratum. Doumer, a colleague of Arsonval, was so impressed with three cases of arrest of fits by voltaization of the abdomen that he brought the attention of the matter before the French Academy of Sciences.

Second only in importance to the colon in this respect is the stomach. The state of the latter in regard to dilatation and stagnation, to prolapse, etc., will doubtless be fixed for each case in the future by radiography. The gastric crises which occur so frequently even in sound subjects and no doubt are essentially preventable may perhaps be foretold and prevented by this resource. As a matter of routine I have all my epileptics with grave digestive disorder *x*-rayed. Now that it is possible by means of *x*-rays to determine the points or parts of intestinal stasis in constipated epileptics we are likely to see a more exact physical therapy of movements,

massage, and electricity applied to overcome the defective function. It will also be possible to determine the value of such lines of treatment by subsequent *x*-ray analysis of the individual case after the special therapy has been used. Even though such physical therapy may not be efficacious in entirely overcoming the special defect causing the constipation, its employment may be safely advised until more drastic surgical procedure, such as ileosigmoidectomy, may be found necessary finally.

Notwithstanding hydrotherapy, with the exception of carefully given lukewarm baths, is condemned by many, the same has not been my experience. With very few exceptions I insist that all my able-bodied epileptic patients shall take cold douching or the cold tub at least once a day. This point is doubly necessary if a bromide therapy is followed to counteract the circulatory depression entailed by the latter drug. In the robust class which, by the way, includes a very large number, I even add salt to the baths for extra stimulation. Sea baths, electric light baths, carbonic acid baths, mud baths, etc., may all be applied in special cases. While it may be true that as a class the metabolism of epileptics is not greatly defective, their defective power of elimination of waste products does not admit of doubt, even though the vicious depression of sedatives be ruled out. Again, it is rather popularly held by the laity as well as the profession that anything which overheats the epileptic is not well for him; here, again, the principle I have just enunciated holds doubly true. Some extreme views and much discrepancy in statements upon this point are doubtless due to the fact that while one has in mind a vigorous epileptic with relatively few seizures, another refers to hopeless cases with frequent attacks. Several years' experience at the Craig Colony for Epileptics proved to me that the extreme of exacting over-strenuous exercise, especially attended by mental excitement, such as keen competition in football and baseball matches, invariably worked harm to the participating epileptic subjects. The equal harmfulness of vicious idleness in this class is already of too common observation to most of us to warrant further comment.

While it may be questioned that any subject has ever been cured solely by making him into a vigorous, robust man, yet this principle should be one of the main points to be considered in any plan of therapeutics. Moreover, the hardening process in the epilepsy of childhood has specially prophylactic powers.

The universal use of caloric feeding has brought out that many epileptic dietaries are several hundred calories short of theoretical requirements. This is a point of special significance inasmuch as the gourmandizing tendencies of the epileptic are proverbial and only too often his dietary is harmfully reduced in consequence. It has not, however, been shown that deficient allowance of food increases convulsions, and if a low diet is prescribed in subjects, especially conjoined with considerable rest and isolation, the same may be a positive benefit in epilepsy.

A great deal continues to be said and written on salt-poor and salt-free diets, and while there are many enthusiasts for the latter, others contend that a salt-poor diet not only answers all practical purposes but that this is furnished automatically by the ordinary milk-vegetable regimen, so that it gives no trouble in administration to either patient, attendant, or physician. The elimination of salt as seasoning, and also to some extent in cooking, replacing it with sodium bromide, is a simple and effective resource. In some cities in Germany breads and flours, zwieback, etc., have been prepared in which sodium bromide is substituted for the chloride. No doubt there are individuals who benefit greatly from rigid exclusion of salt; but on the other hand death from status has occurred under this same plan.

In regard to alcoholics, Bratz found that two bottles of beer daily do not aggravate the average case at Wuhlgarten, but he does not advocate its use and evidently only means to show that we may accuse the wrong factor in certain cases. The objections to a moderate amount of meat and purins are conceded to be chiefly theoretical. An excess of meat gives rise to the possible formation in the intestine of poisonous or injurious cleavage products. In regard to purins Ziehen never allows his patients to take bouillon, placing this in the class with coffee, tea, and spirits. In carbohydrate intolerance cereals must be avoided.

We now come to a phase of treatment second only to psychotherapy in regard to novel features. For while gastroenteric disorders are the longest known of any, the part which they play has not been fully realized until quite recently. The late Ebstein, in an article written in 1911, speaks earnestly of the gastroenteric factor as being almost the key in unraveling the mystery of convulsions—not only spasmophilic but epileptic in the strict sense. If many convulsions in epilepsy are psychogenous, many others may be enterogenous—due not to epilepsy *per se*, but to associated or underlying spasmophilia.

The renewed importance at this period of the subject in question is due chiefly to the revolutionary diagnostic uses of the *x*-ray in locating mischief in the gastroenteric tract as previously noted. Our knowledge of colonic activity is being added to enormously. The course of a test meal can be traced accurately from mouth to rectum, and the relations which subsist between yesterday's and to-day's ingesta properly appreciated. Aside from universal types there are individual anomalies due to mechanical faults in the colon. There seems to be little doubt that if the latter defect could be eliminated a certain contingent of epilepsy might be greatly benefited. Alexander (1910) writes exhaustively of this subject and refers to the cures of epilepsy by Lane with ileosigmoidostomy, while La Place of Philadelphia claims to have cured a case by removing mechanical obstructions.

If the rationale of the colonic factor depends on putrefaction and absorption of toxic substances like cholin, this result must be due largely to the activity of putrefactive bacteria. It is not difficult to fix the status of this question by urinary tests, but the mere presence of indicanuria in such cases is not conclusive, for intestinal autointoxication need not depend upon the amount of toxic material formed, but rather on the personal susceptibility, perhaps increased by previous sensitization, on which there is a wide difference of opinion.

There remain for consideration surgery and drug therapeutics. In regard to the former it is doubtful if the past few years have contributed a single new fact of importance. Well indicated operations fail and paradoxically good results seem to follow random operations done for their own indications. Removal of an irritating peripheral focus may perhaps cause the cessation of spasmo-

philic convulsions in an epileptic without in any way modifying the disease itself. For instance, Alexander's operation of fenestration of the dura, performed upon idiopathic epileptics in whom the attacks begin focally or in which there remains throughout life a Jacksonian order of muscular invasion of the fit, has nothing specially to recommend it. Many have reported failures after undertaking this operation, but it must be admitted they did not accurately follow the surgical technique laid down by Alexander. However, even in those who have followed this surgeon's technique carefully the results so far have been uniformly poor. Even Alexander's main reason for the operation, a focal edema of the pia arachnoid and epipial space, has not been confirmed by other observers so far as I know. I have known of but three cases personally observed in which this operation was undertaken, and no good results followed its use.

In regard to the drug therapy the fact is now conceded that drugs from several classes of remedies possess antiepileptic powers, and it is conceivable that any narcotic, sedative, hypnotic, antispasmodic, or cardiovascular depressant may favorably modify convulsions for a short time. Hence it need not surprise us if new drugs like "epileptol" and "crotalin" reduce the number of seizures in selected cases; or that old time-honored prebromidian drugs when tested to-day often show marked powers in this direction. Under this head we may mention silver salts, zinc salts, the valerians, cannabis indica, belladonna, and all the mydriatic alkaloids, codeine, etc.

It need not startle us to be told that borax has antiepileptic powers, and that veronal and other hypnotics exert some control over convulsions. We should be more surprised if all these drugs did not exhibit some of this power; but that any or all of them produce permanent good results one may have grave doubts.

Whatever plan of treatment is used must be exhibited continually for years and it is only too evident that none of the proposed measures can supplant the bromides save when the latter cannot be tolerated. And nine-tenths of the intelligent effort is being directed toward preparing bromides in a form which can be tolerated.

The question is not between bromide and some other drug, but between drug treatment and drugless treatment. If drugs have to be used they must be chiefly bromides. That this view is the one commonly accepted is shown by the great activity in preparing synthetics containing a large per cent. of bromide. Perhaps the chief objection to these is and must be the expense involved. Sodium bromide is one of the cheapest drugs and is not likely to be supplanted. It is palatable and agrees well, and it is difficult to see how it can possess any marked inferiority to the new synthetics.

For years routine sedative treatment has so usurped the field of attention in epilepsy that many physicians have made no serious attempt to really understand the nature of the difficulties confronting them. This has led to great inroads of special quacking in legitimate fields of medicine such as eye-strain and other reflex explanations, and a host of vampire patent remedy venders. Now that we are in the day of real scientific inquiry as to the nature of the individual case, especially the factors of defective bodily functions, there is more hope that we shall know the influence which such disorders have upon the mental and neural make-up of the spasmophilitic constitution. I have detailed elsewhere my views opposed to the sedative plan of treatment ("Curability of Idiopathic Epilepsy with Report of 29 Cures," *Archives of Internal Medicine*, January, 1912, Vol. 9).

Bromides should not be used until everything in the physical make-up, in circulation, digestion, and the like important functions is set quite right, and then the sedatives need to be applied with the greatest caution as they have such potency to injure the functions most desired to remain normal.

A word as to the so-called detoxicating or antiautotoxic regimen. This does not lie in the application of a single resource or a few, but represents the application of most of our modern resources at the same time. Many measures are advocated for no other reason than the possible diminution of the sum of the autotoxic poisons. Sweating and purgation are old but very important resources. During the Bouchard period "intestinal antiseptics" came into vogue and their influence is still in evidence, for now and then an author reports good results from the use of salicylic acid, bismuth, naphthol, and similar drugs, and the supposed antiepileptic power of borax and boric acid is believed by some to be bound up in this form of activity. Much of dietetics and all of the measures securing intestinal drainage and sterilization are based on the idea of detoxication, so that right or wrong the latter conception underlies three-fourths of our modern ideas of treatment. Personally, I believe it is the most rational view to take in applying any general plan of therapeusis in epilepsy.

Finally, it is unfortunate that the disease of epilepsy should be looked upon from two radically different viewpoints in its nature and treatment: first, that the mechanism of its production is a general chemical poison, from some defect in nutrition in bodily functions, thus ignoring the spasmophilitic constitution, and secondly, that of the phenomena of the fit, which some would make all there is of epilepsy, the subject showing his disease only at the time of seizures, and therefore the disease has its pathogeny chiefly or solely in a progressive and irritating form of marginal or cornual gliosis of the brain. The one school either ignores the brain changes or counts them only as results of the attacks, while the other thinks attention to the defects in the metabolism and elimination of waste products in the epileptic is a remote, hypothetical, and visionary view of causation. We have yet to educate ourselves to paying equal attention to both, and neglecting no broad biological concept of the disorder whose treatment continues to be a stumbling block in neurological therapeutics.

84 East Fifty-sixth Street.

DISEASE AND GENETICS.

By R. G. ECCLES, M.D.,

BROOKLYN, N. Y.

It is hardly likely that any one will deny that the properties of matter reside in and are inherent qualities of the same. How, otherwise, could they be properties of matter? Pure sugar possesses sweetness, whiteness, and a definite crystalline form with other qualities that constantly occur in it. Dissolve, and thus separate the sugar units as much as we choose, and so long as they remain intact sugar molecules these properties persist. Split them, chemically, into fragments smaller than the sugar molecule, or rearrange their inner atomic

structures so as to produce isomeric groupings and, instantly, all distinctly sugar qualities vanish, while other new and quite unlike ones take their places. Like sugar every distinct chemical entity has certain qualities that belong to each particular atomic grouping and to no other. Such groupings may vary their color by varying their crystalline form, and thus producing a different effect on light waves, but even this quality is specific. To this rule the substances constituting the building materials of our bodies show no evidences of being exceptional. Their properties all appear to be inherent in their molecules. Bone, skin, hair, muscle, nerve, bark, wood, etc., are what they are by virtue of their molecules. Inasmuch, however, as the qualities of all of these are hereditary qualities, who can give any reason why we should not look to the molecule as the basis of heredity? To changes in the molecules of all of these must be due their variations and to their unchanged, persistent sameness must be credited the persistence of heredity. Since chromatin granules, chromosomes, and other cell structures, as well as the tissues and organisms which they collectively produce, are all built of chemical molecules, their properties must, somehow, be due to the molecules out of which they are constructed. How, then, can any one hope to solve the problem of genetics until we have solved the problem of its relation to the molecule? "This vertebrate," says Pouchet, "has muscles, organs of senses, viscera like the various animals from which it is supposed to have proceeded. But there are, further, in it living substances of a special order, cartilage, and bone, which are real chemical species. When, how, and under what circumstances did these substances appear which we find identical as to themselves in all vertebrates which no other existing animals possess? * * * We want to be told through what internal chemical actions these organic compounds appeared; these clearly defined substances the presence of which establishes an absolute distinction between vertebrate animals and the worm or molluscs from which they are supposed to descend."[1] Will mutationists, Mendelians, and all who hold to the faith that nature's biological progressions occur through leaps, kindly consider Pouchet's question and say how it is possible for such substances to evolve except by an evolution of their respective molecules? Either the appearance of these substances in the higher organisms betokens a miracle or there must have been an evolution of a molecular character. No third possibility seems conceivable. But, if the evolution was a molecular one, then it follows that the units taking part in heredity are so exceedingly minute that a de Vriesian mutant is comparable thereto about as Mount Everest might be compared to a grain of sand at its base. In such organisms as have been chemically studied there have been found minerals, fats, carbohydrates, and proteins. What, other than these, can be credited with being the bearers of many or most hereditary qualities? Why should we not, with Loeb, "naturally think first of definite chemical compounds as the bearers of hereditary qualities?"[2] What except the myosinogen, and other molecules of a muscle, can constitute its form or cause its contractility? "The protein molecule," says von Noorden, "just as the cell and the protoplasm can transmit and hand down its form and specific energy to a newly formed molecule. * * * One part of the problem dealing with the transmission of vital properties—in fact, a most important because a fundamental one—is the transmission of the protein molecule."[3]

The chief quantitative constituent of organisms is, doubtlessly, water. It is the most important of the mineral constituents of our bodies, and no living form could have existed without it. Its wonderful inherent ability of being able to build up crystals of exquisite form we are all familiar with. "Those fern-like forms," says Tyndall, "which on a frosty morning overspread your window panes illustrate the action of the same (crystallizing) force. Breathe upon such a pane before the fires are lighted, and reduce the solid crystalline film to the liquid condition, then watch its subsequent appearance. You will see it all the better if you look at it through a common magnifying glass. After you have ceased breathing, the film, abandoned to the action of its own forces, appears for a moment to be alive. Lines of motion run through it; molecule closes with molecule, until finally the whole film passes from the state of liquidity, through this state of motion, to its final crystalline repose." Again he tells us that "Latent in this formless solution, latent in every drop of water, lies this marvelous structural power, which only requires the withdrawal of opposing forces to bring it into action. * * * The common matter of our earth—'brute matter,' as Dr. Young pleases to call it—when its atoms and molecules are permitted to bring their forces into free play, arrange themselves, under the operation of these forces, into forms which rival in beauty those of the vegetable world. And what is the vegetable world itself but the result of the complex play of these molecular forces? Here as elsewhere throughout Nature, if matter moves, it is force that moves it; and if a certain structure, vegetable or mineral, is produced, it is through the operation of the forces exerted between the atoms and molecules. These atoms and molecules resemble little magnets with mutually attractive and mutually repellent poles. The attracting poles unite, the repellent poles retreat, and vegetable as well as mineral forms are the final expression of this complicated molecular action."[4]

We are yet far from being able to trace the path by which these polar forces, to which Tyndall here refers can, through colloidal cell material, direct the dendritic hereditary morphology of plants. We know that such forces exist and we likewise know that during mitosis, when cells are about to divide, there occur numerous chemical changes that indicate freedom of molecules that might be of a directive quality. But, whether Tyndall's theory is or is not true we are constrained with President Schäfer to bow to the conclusion that heredity "is one of the questions the eventual solution of which we must look to the chemist to provide."[5] The chemist is rapidly working his way thither and it might be well for some of our biological evolutionists to take heed to what he is doing. His analyses show that no mineral substances that enter into the construction of organisms can be credited with qualities specific for the organisms in which they occur. They cannot therefore bear any such relationship to such organisms as water molecules bear to the magnificent crystal fronds that grace our windows on very cold nights. They do not vary in kind from organism to organism as we might expect them to do if they took a directive part in the morphology of organisms. The chemist has also found that "not only do identically the same sugars and fats occur in many species of plants and

animals, but many of these are common to both forms of life," so cannot possibly be related to the forms in which they occur, as water molecules are related to water crystals.[6] He has, therefore, ruled out every known material constituent of animal protoplasm, *except protein,* as being in any way a pronounced agent in producing the differences that occur between animals and animals and, with one possible exception, between plants and plants. If any known material constituent of cells takes any part in directing specific morphology it must be protein. Nothing else known to man can meet the numerous requirements and it does so to so startling a degree of fidelity that we must conclude that if it is not the chemical cause it well might be. In whatever organism it is found its chemical structure parallels, perfectly, in its variations the variations of that given organism from its biological kindred. Kossel tells us that while we cannot at present fully comprehend the rôle of the proteins, "we must assume that many of the enigmatical properties of living matter depend on this activity of *intact* protein molecules. We can obtain," he says, "some idea of the possible variety in the combinations of the protein baustein (building-stones; amino acids) by recalling the fact that they are as numerous as the letters in the alphabet which are capable of expressing an infinite number of thoughts. Every peculiarity of species and every occurrence affecting the individual may be identified by special combinations of protein baustein, that is to say, by specific proteins. Consequently, we may readily understand how peculiarity of species may find expression in the chemical nature of the proteins constituting living matter, and how they may be transmitted through the material contained in the generative cells."[7] This same idea is expressed by an editorial writer in the *Journal of the American Medical Association,* who declares that "We know that the characteristics of different cells and tissues depend chiefly or solely on their proteins, and the proteins in turn differ from one another in the proportion of the various constituent amino acids that they contain. Each class of animals has cellular proteins and blood proteins specific for its own kind, as shown by precipitin tests, and it is possible that the proteins of every individual differ in some respect from those of every other individual."[8] Guyer, in discussing the same subject, says: "Our whole scheme of natural classification demands just such a physical basis as is depicted for the structure of the protein molecule."[9] In bacteria, moulds, fungi, algæ, grasses, herbs, trees, protozoa, sponges, sea urchins, worms, snails, fishes, reptiles, birds, beasts, and men, *identical kinds of amino acids constitute the building stones of the respective protein molecules.* They differ solely in the proportions, and in the relative positions which they occupy in the different kinds of molecules. As these proportions and relations change so their crystalline forms change when they are crystallizable. They are all bound together in these molecules in the same manner, *i.e.* by the aid of an enzyme and amboceptor (co-enzyme) their acid and basic side chains are brought together and linked in union and these unions we call proteins. The process of union in every instance seems to be the same. How the right amino acids reach the right place at the right time, within each kind of molecule, constitutes the chief secret of living matter—a secret which has baffled the biochemists for many years. If we could but discover this secret of the sifting power of cells there would be but little trouble in our producing specific protein molecules. Emil Fischer has already taken the primary steps in his work of building up polypeptids. He makes the proper unions, but is unable to guide the right amino acids, at the right time, to the right places, so as to produce our specific proteins.

We have stolen from organic nature far more of her chemical secrets than the average physician, or naturalist, who is not something of a biochemist, is aware of. It is not generally known that our present knowledge in this direction is, in the main, very definite and quite exact, so far as it goes. It is no longer the vague, nebulous thing it was when most of the readers of this were college students. There is now no room for reasonable doubt of our having succeeded in securing a clear understanding of the nature of the constituent fragments out of which proteins are built. There is a complete consensus of the competent and this is expressed clearly by Taylor when he says that "No matter in what manner and with what reagents (different acids in different concentrations, different alkalis in different concentrations, ferments, steam), the hydrolytic cleavages are accomplished, the end result in the yield of amino acids is the same. In other words, the hydrolysis does not form amino acids, it does not alter them, it does not convert them (one) into another; it simply sets them free, their isolation thereafter depending upon particular chemical methods. * * * The reactions of hydrolysis do not add to, subtract from, or in any way alter the component bodies that existed preformed in the original substrates. The more the technique of the hydrolysis of the proteins is perfected, the more certain has it become that the component amino acids exist preformed in the molecule of protein."[10] This fact being firmly established puts us upon a secure footing in respect to the parallelism to which reference has been made, between the chemical make-up of the various proteins and the morphology of the organisms containing them.

As hair differs from the feathers of birds, skin from the scales of fishes, our color from that of a negro, and our nervous equipment from that of a worm, so differ the molecules that constitute these respective tissues. The albumins, globulins, glutelins, prolins, albuminoids, histones, protamins, nucleouproteins, glycoproteins, phosphoproteins, hemoglobins and lecithoproteins of different organisms, all show differences corresponding to the differences of the organisms in which they occur. They all carry characteristics that are distinctly hereditary. These characteristics cannot possibly reside in anything other than their molecules. As the numbers of these molecules increase growth becomes evident. With no increase in their numbers there can be neither growth nor multiplication in any organism. The heredity of the cell, as well as the heredity of the organism, thus resolves itself into the problem of the qualities of molecules, or, as Guyer puts it, "The mechanism of heredity would seem to be not so much a local problem of nucleus and cytoplasm as of fundamental species substances, probably mainly protein in nature."[11] But from whence come these species substances? How and where do they originate within the cell? "Kossel concludes that the formation of new organic matter is dependent on the nucleus, and that nuclein in some manner plays a leading rôle in this process;

and he makes some interesting suggestions regarding the synthesis of complex organic matters in the living cell with nuclein as a starting point. Chittenden, too, in a review of recent chemico-physiological discoveries regarding the cell, concludes: 'The cell-nucleus may be looked upon as in some manner standing in close relation to those processes which have to do with the formation of organic substances.'[12] Mann states that he is unable to reach any other conclusion than that the nucleoproteins are the "agencies by which amino acids are built up into cell plasm."[13] Inasmuch as the nucleoproteins are chemical constituents of what microscopists call chromatin this statement seems to confirm the statement of Minchin when he tells us that "There is no evidence that chromatin, within or without the nucleus can ever arise *de novo* or in any way except from preexisting chromatin, the particles of which grow and multiply as the result of processes of assimilation such as constitute the most essential characteristics of living substances generally." Again he says: "Judged by microchemical tests, no two samples of chromatin can be considered identical in composition, whether from different cells or even from the same cell at different times."[14] The significance of these statements of Minchin's can be readily seen when we learn from Wilson that "In the shark *Pristiurus* * * * the chromosomes, which persist through the entire growth period of the egg, undergo the following changes: At a very early stage they are small, and stain intensely with nuclear dyes. During the growth of the egg they undergo a great increase in size, and progressively *lose their staining capacity*. At the same time their surface is enormously increased by the development of long threads which grow out in every direction from the central axis. As the egg approaches its full size, the chromosomes rapidly diminish in size, the radiating threads disappear, and the staining capacity increases. They are finally again reduced to minute, intensely staining bodies which enter into the equatorial plate of the first polar mitotic figures. At the beginning the chromosomes measure, at most, 12 micros (about 1/2000 inch) in length and ½ micro in diameter. At the height of their development they are almost eight times their original length and twenty times their original diameter. These measurements show a change of volume so enormous, even after making due allowance for the loose structure of the large chromosomes, that it cannot be accounted for by mere swelling or shrinkage. The chromosomes evidently absorb a large amount of matter, combine with it to form a substance of diminished staining capacity, and finally give off matter, leaving an intensely staining substance behind."[15] All this agrees exactly with the supposition that the chromatin of the chromosomes is concerned in the building up of protein molecules. When its staining capacity is great it appears to be almost entirely composed of nucleic acid, the substance within it that stains freely with nuclear stains. As the amount of basic protein increases the staining power must, naturally, decrease. When this newly formed protein is discharged into the cytoplasm the staining power, of course, must return. "In inverse proportion," says Wells, "to the degree to which this acidity (of the nucleic acid) is neutralized by proteid groups in the nucleoproteid molecule, the nucleo-proteid will show affinity for basic dyes."[16] If the protein molecules of the soma plasm are, as the facts seem to indicate, products of the chromatin granules, then it follows as a probable conclusion that within, or upon, these granules the orderly sequence, proportions, and time control, of the enzyme-conducted syntheses of amino acids occur, by some such means as specific osmosis through their walls, or specific absorption upon their surfaces, of these acids. Chromatin granules, from this viewpoint, are, as it were, a sort of type-setting machines for the orderly putting together of the amino acid type-alphabet. As our bodies contain somewhere near twenty different kinds of proteins we can consider them as twenty living volumes of phylogenetic history. How faithfully they portray this history can be seen when they are read in the light of the precipitin reaction. Let us first ascertain that part of the story told by the blood serum.

As the reader may wish to test the method the following condensed statement will be appreciated: "A rabbit is injected intraperitoneally with 10 c.c. of human blood serum at intervals of a few days until from six to eight injections have been given so that there is formed in the animal's blood a substance that will produce a precipitate in diluted human serum. The animal is now allowed to rest for a week, after which its blood is drawn and the serum obtained. The blood to be treated, if fresh, is diluted 100 times, but if dried, the material is soaked with distilled water and the filtered solution is mixed with an equal volume of double normal salt solution (1.2 to 1.8 parts of sodium chloride to 100 parts of water). To the clear solution thus prepared a few drops of the serum of the immune animal (the rabbit) are added and the mixture allowed to stand to see whether a precipitate will occur. If the material contains human blood, a precipitate will occur within half an hour. The precipitin is specific for human blood as distinguished from that of other animals except those of the ape family."[17] If dog's serum has been injected into the rabbit instead of human serum the precipitin in the rabbit's blood would have been specific for dogs and not for humans. If horse's serum had been used for injecting, then the precipitins would be specific for horses and not for dogs or humans. Whatever animal is chosen, from which to take the injected serum, the precipitin is specific for that animal, and its close of kin, but for no others. Other animals besides the rabbit can be used into which to inject the serum and the precipitin will be formed in the blood of that animal.

It having been suggested that the precipitation might be due to physical causes, Arrhenius, the well-known Swedish chemist, made a thoroughly critical study of the subject and reported that "it is perfectly clear from many circumstances that the precipitation is a chemical process."[18] The further question being raised as to whether the precipitin might not be an enzyme he replied that "the experiments with precipitins lead to the conclusion that they are really bound in the precipitates and do not act as catalytic agents."[19] So thoroughly established has scientific confidence now become concerning the reliability of the precipitin reaction that it has taken its place as one of the certainties of forensic medicine. Schulz has even developed a method of volumetrically estimating special proteins by its means. In an actual test of his method it was found that one part of extract of horse flesh in 820 parts of diluting material could be determined to within about 2.5 per cent. of the actually added flesh.[20] It is now possible, by means of the precipitin test,

to tell the kind of animal from which a given sample of blood came and a human blood stain can be identified, as human, when found on clothing or other articles, after the lapse of many days. Blood stains of dogs, cats, hogs, horses, chickens, or sheep can be told apart with but little difficulty. There is an element of difficulty in telling a human blood stain from that of a chimpanzee, but with care, this, too, is possible. Very old stains sometimes might mislead, but generally "dried bloods give the reactions after the lapse of considerable time, months or even years," and Nuttall declares that this "has been fully established."[21] Species of animals that are closely related to each other, as the ape to man, the goat to sheep, or the dog to the wolf, while giving precipitates with the same precipitins do not give the same amounts. The animal whose serum was injected, so as to form the precipitin, gives with its serum the largest volume of precipitate and it appears in the quickest time. If dog serum were injected into the rabbit then the serum of any dog would give a denser precipitate than would the serum of a fox. The serum of a wolf, however, while giving less pricipitate than that of a dog would give more than that of a fox. The degree of consanguinity is in this way revealed by the test. "It is a somewhat startling verification of the consanguinity of man and the higher monkeys," says Ewing, "that the blood of the chimpanzee gives 90 per cent. as much precipitum with humanized rabbit serum as does the blood of man himself, while the blood of lower monkeys yields only one-fourth or one-third as much. The chimpanzee thus appears much more nearly related to man than to the common Rhoesus monkey."[22] Arrhenius tells us that "A very interesting instance of this behavior is given by Hamburger in the action of the serum of a rabbit treated with sheep serum on the sera of three different animals, viz., sheep, goat, and bullock which are so closely related to each other that all yield precipitates with the said rabbit-serum. As is natural the sheep serum yielded the most voluminous precipitate; next comes the goat serum, which animal is most closely related to the sheep; and the least quantity of precipitate is given by the serum from the bullock, which is less closely related to the sheep than is the goat."[23] These reactions all indicate that the precipitated protein molecules of different species of animals, when the same type of protein is considered, grade into each other, in their chemical qualities as their blood relationships grade. They also prove that there is a quantitative relationship among the molecules of any given tissue protein corresponding to the species relationships of the organisms in which they are found. As gradually as changes any given type of protein molecules so changes the species. Where no changes occur in the protein molecules no changes occur in the species. As is the amount of change found among the molecules so is the amount of change found distinguishing the species from which such molecules come. The entire hereditary outfit of every species is paralleled in volume by precipitin differences in the different protein molecules which they contain.

We have seen that 10 per cent. change in the serum of a chimpanzee as compared with that of a man represents roughly by our crude method of estimation, about 10 per cent. of variation in species difference. We have also seen that a 70 per cent. change in the precipitin reaction indicated a correspondingly great change in the external form of the monkey compared. On getting far enough away, so that no human-like characteristics remained, no precipitins could be formed. When 90 per cent. of the serum of a chimpanzee is chemically precipitated by the same precipitating reagent as throws down 100 per cent. of human protein molecules, what else can it mean than that 10 per cent. of the serum molecules have varied sufficiently from the homologous blood serum with which the common ancestors of both started so as to differ in their chemical affinities to this extent? All the other molecules may have changed a little, or they may not have changed any, but if they have changed at all it is not enough to alter their power of uniting with that particular precipitin. The reaction tells us quite unequivocally that nine out of ten of the molecules of human blood serum are very nearly, or perhaps wholly, identical in chemical nature with those found in chimpanzee blood. The chemical gap widens as widen the variations in form and function until at last there is not sufficient resemblance between them to show kinship. As Nuttall says: "It is a remarkable fact * * * with the Anthrapoidea, and this applies to other groups of animals, that a common property has persisted in the bloods of certain groups of animals throughout the ages which have elapsed during their evolution from a common ancestor, and this in spite of differences in food and habits of life. The persistence of the chemical blood relationship between the various groups of animals serves to carry us back into geological times."[24] What is no doubt the most striking illustration of the sameness in the chemical nature of the protein molecules linking living with extinct animal forms is the one related by Friedenthal. He has shown that animals "immunized to elephant's blood produce precipitins that react with the blood obtained from a Siberian mammoth which had remained frozen in the ground since the diluvial period."[25] Here is evidence that a modern-made precipitin was able to chemically unite with protein molecules produced, probably, many thousands of years ago and that were protected from hydrolytic cleavage by persisting cold. Here, too, is evidence that ancient blood and modern blood are really akin. Precipitins as an index of evolution link together every so far tested organism. Experiments in great numbers have shown that they are producible for birds, and beasts, fishes and reptiles, plants and protista. Wherever there is evidence of kinship, as seen in our scientific classifications, there is found precipitin evidence telling the same sort of a story. The rule, with one apparent exception, is universal. Wherever we tap the proteins the radiations of their kinship appear. The whole fabric of life, in its warp and woof of connected species, shows this gradual grading of proteins with proteins through and through every structure. At every point we get evidence of the almost infinitely minute selections of fitnesses. At every point the precipitins demonstrate that the heredity qualities come and go in quantitative degrees so fine that they are only measurable as molecules. The finest microscope ever constructed is far from being sufficiently powerful to detect relatively immense numbers of them when grouped together. Suc' a condition of things is inconceivable as having any natural cause, unless there has been always, and at every point in evolution, an incessant sifting for destruction of such molecules as failed to vary as varied the environment. The fact that in the whole ascending scale of living things certain kinds of molecules were constantly disappearing while certain others as constant-

ly took their places can only mean a survival of the fit in the struggle for existence. The fact that fit molecules kept increasing in numbers while unfit ones disappeared, and this *pari passu* with the evolution of every kind of organism, means natural selection or miracle. The fact that the precipitin reaction is not a restricted bit of phenomenon, but something that is seen to have gone on everywhere, and in every living thing, for all past time, appears to the writer to be strong evidence in favor of the view that the incidence of natural selection must have been much less upon the individual than upon the protein producers of the germ plasm. Its immediate cause would seem, likewise, to have been always nearly the same, always something that selected for destruction certain kinds of protein molecules. The perishing as well as the surviving units are always and everywhere protein molecules. The survival of fit molecules would, naturally, mean the survival of the individuals carrying such molecules. The disappearance of unfit molecules, thus making way for fit ones, would likewise be a cause of survival of the individuals from whom they disappeared.

Strong as is the evidence, from the study of the precipitation of proteins by precipitins, that a gradual variation has been constantly going on in protein structures along the paths that radiate from species to species, and from genera to genera, it has been rendered very much stronger by the research work on hemoglobins. The molecules of these proteins being readily crystallizable can, by successive crystallizations, be procured in a very pure state and their crystal forms studied. Measurements of their angles have shown conclusively "not only that corresponding hemoglobins are not identical, but also that their peculiarities are of positive generic specificity, and even much more sensitive in their differentiations than the 'Zooprecipitin test.' Moreover, it has been found that one can with some certainty predict by these peculiarities, without previous knowledge of the species from which the hemoglobins were derived, whether or not interbreeding is probable or possible, and also certain characteristics of habit, etc." Dr. Reichert, whom I here quote, further says: "This method of studying the hemoglobins of various species of animals furnishes the systematic zoologist a means of testing his findings in regard to the relationships of different species and genera, and should prove a valuable adjunct to the morphological data upon which he relies for establishing such relationships. The crystallographic characters that have been recorded in the descriptions of the hemoglobins of species, and especially the tabulations of them for the different groups of animals studied in their research, show, as has been pointed out, that the characters of the crystals of a genus are specific for each genus. The comparison of the crystals of related species or genera show how closely they may approach each other as regards this character. If we take, for example, the genera *Canis, Vulpes,* and *Urocyon* of the family *Canidæ* they will be found to be as closely related to each other in regard to the crystallography of their hemoglobins as are the species of a single genus in other cases; for example, as the crystals from the baboons of the genus *Bopio* are to one another. Indeed the dingo (*Canis dingo*) varies more from the normal dog type in regard to these characters than the species of the same genus *Canis* in general vary from the species of *Vulpes* and *Urocyon.* * * * On comparing the crystals of the few species of primates that were examined a striking similarity may be seen between the α-oxyhemoglobin crystals of the baboon and those of man. The β-oxyhemoglobin crystals found in the baboon were not observed in the crystals from the human species, but the γ-oxyhemoglobin crystals of the baboons closely resemble the corresponding crystals observed in human blood. In this case the parallellism of the crystals from the two genera is shown in the two kinds of oxyhemoglobin crystals."[26] The reader can no doubt see that we have here proof of the most convincing character that these protein molecules gradually vary from species to species in a manner that parallels their morphology. It is, therefore, among protein molecules that we should look for the fundamental facts of heredity. It is among them that we ought to search for the causes of variation. It is to them that we should go, if we really wish to determine why, in all upward evolution, some disappear steadily and gradually as if being picked out for destruction by some selecting agent. Inasmuch as it is common knowledge that the lives of the cells of both plants and animals are now, and long have been, menaced because of the edibility of their molecules, why should we refuse to put these two facts together and deduce from them their one and only conceivable meaning? Guyer does not hesitate in tracing the crystal forms of the hemoglobins to their molecular configuration when he says: "In hemoglobin, one of the few crystallizable proteins, the crystals of each species of any genus, while possessing a constant individuality, all belong to the same crystallographic system and generally to the same crystallographic group of the same system. * * * This isomorphism must signify in all probability correspondence in the fundamental chemical constitution and molecular configuration of respective hemoglobins."[27] But why stop at this point and not ask ourselves whether there is, or is not, some agency at work directing these molecular variations? What is it that is selecting for perpetuation certain types of molecules while dooming others to destruction and final disappearance? *Is it not a very suggestive fact that the same substances as are attacked by disease-germs are the identical substances that are now known to change their structures during phylogenetic progress?* Surely there is something more than coincidence in a relationship such as this when it is perpetuated generation after generation, age after age, and geologic epoch after geologic epoch. Nor is the evidence of its existence confined to the discoveries of serologists and crystallographists alone. Biochemists confirm their findings. Osborne, who has made a life study of the subject, in conjunction with other educators, and with his pupils, declares that "the chemical constitution of the proteins is closely connected with the biological relations of the forms of life that produce them, and that the morphological differences between species find their counterparts in the protein constituents of their tissues."[28]

When an attempt is made to read into these marvelous modern discoveries regarding the foundation facts of living organisms what they most likely mean for genetics, we are astonished at the meagerness of the references made to them by writers on heredity. We feel, when reading such books, much as if listening to a performance of the play of Hamlet in which the Prince of Denmark fails to make his appearance upon the stage. Why do they not take the clue from Verworn when he declares that modern physiology is little more than the

chemistry of the proteins?[29] Perhaps we are not justified in expecting anything more satisfactory than this when we discover how little many chemists know about what is going on in pathology, or biologists about what is being done in chemistry. There was a time when medical men constituted the "Naturalists" of the world, but the old genus Naturalist has become almost as scarce on our planet as are teeth in the mouth of a hen. Specialization has all but extinguished this race. Many of our most far-seeing thinkers are deploring the widening of the gaps between sister sciences and are protesting against its perpetuation. Opie has, evidently to his regret, found that "The pathologic problems are unfamiliar to the physiological chemist, and the pathologist is poorly prepared to solve them."[30] Wheeler aptly refers to "the characteristic myopia of one who sees not the forest because he is studying the venation of the leaves."[31] Poulton deplores the all too patent fact, that "the home of information is in this country [England] too often the grave of imagination."[32] Bower tells us that "It is not every worker who understands the general scheme of which his labor forms a part, however well he may be carrying out his own particular research. And, furthermore, since there is seldom any masterhand directing the efforts of individuals, some workers, having a perverted idea of the general scheme, may lay out their own investigations on mistaken lines, and their labor may be in vain."[33] Ganong presents the case in a forcible manner and half suggests a possible remedy. He says: "The expansion of science in our day has been so vast, the literature has become so voluminous, the specialization of method and thought are so extreme, that it is becoming a serious question how the results of new research, when not of a sensational nature, can be quickly, accurately and adequately incorporated into the general mass of our knowledge and made available to the intellectual or economic uses of our race. Every scientific man has witnessed the ignoring of new truth long after its announcement, and the repetition of old error long after its disapproval, not alone in popular information and literature, but even in the best scientific textbooks; and this maladjustment between scientific research and general knowledge waxes constantly greater. The trouble is plain: we have no recognized collectors of knowledge, scholars whose business it is to stand between the investigators and the general user of knowledge and to interpret correctly the results of the one to the other."[34] This state of affairs among scientific workers supplies an ample explanation for the fact that students of genetics have ignored, and still continue to ignore, the important facts herein set forth. Knowing only the popular, and somewhat sensational, aspects of the precipitin reaction they could hardly be expected to apply it at the root of their own subject where it rightly belongs. No wonder, then, that one of the best botanists in the world could write in one of his books that "the material bearers of the hereditary characters cannot be identified with the molecules of chemistry."[35] Inasmuch as they actually do vary in their chemical qualities as vary the species and genera in which they occur, we have in this positive proof that molecular structural qualities are inherited. Since crystallizable proteins vary in their forms, as vary the species in which they are found, have we not in this strong evidence of their carrying inherited qualities? When, by a study of their crystals, an expert can predict the leading characteristics of the genus or species from which such crystals came, can we declare that they are not carriers of heredity? What is there in the body more fundamental than these proteins? What takes a more prominent part in the structure of an organism than these? What, more than these, varies as organisms vary? Whence, if not from these, comes the directing energy that underlies morphology? It is the multiplication of these that makes organisms grow. It is quite true that there must be a mechanism by which the building stones of these molecules are brought together, but does not the whole body of each animal take some part in metabolism? From the moment food leaves the stomach till the time it is completely sifted into the respective amino acids, and these distributed to the cells that need them, are there not membranes to pass having specific osmotic powers? Within the cells are membranes that continue the sifting and continue their aid in bringing the right amino acids to the right place at the right time? Are not certain, presumably unfit, amino acids destroyed before reaching the nucleus of any cell?

The chromatin granules are probably the cell organs in which the synthetic work of constructing the various kinds of protein molecules begins. Such facts as we possess appear to point in this direction. Should, however, a time come when this conclusion should become doubtful the facts relating to the proteins are so certain that some other cell organs would have to be chosen as the regions of the proteins' birthplaces and as the rudimental nuclei (enlagen) of heredity. Nothing else than the proteins, that we know anything about, can be reasonably credited, from a chemical standpoint, with being the carriers of heredity. To credit the chromosomes with being such carriers is but to credit them with being the producers of proteins. Any other conclusion seems to lead to a deadlock between logic and fact. The chromosomes are the carriers of heredity because they are—from this viewpoint—the producers of proteins, and for no other reason that we are able to give. This conclusion is at present ignored by most mutationists and Mendelians, but the time is now here when they must reckon with the chemical facts or be routed as illogical theorizers. They must show why the molecule's heredity is of no importance to them. They must show why its heredity is invariably correlated with the heredity of the organism. The discovery that inheritance is a far more fundamental problem than they have thought it to be puts a new face on the entire subject. They have done good work in supplying us with a wealth of facts that were before unknown or ignored, but in their attempts at explaining such facts they, in turn, have ignored other facts just as important as any they possess and immensely more fundamental, inasmuch as these later facts sink down to the foundation stones of all material properties—the molecules. Truth, in this instance at least, seems to have been found at the bottom of the well of facts. When Punnett tells us that "in the light of our present knowledge we must regard the mutation as the basis of evolution—as the material upon which natural selection works. For it is the only form of variation of whose heredity we have any certain knowledge,"[36] it is quite evident that he has forgotten or overlooked the fact that the molecules of proteins are in possession of a heredity far more fundamental than that of any mutation, and their variations are so constant that they mark the path of evolution at every point. They, and not exclusively the

mutations, are the fundamental material upon which natural selection works.

The mutation view of the origin of organisms, while it may be reasonably maintained as a temporary makeshift by men capable of holding their minds for a long time in suspended judgment, tends to bias the mind of the average man in favor of a belief in miracles. To-day it is the strongest prop that the believer in a miraculous preordained harmony is able to get hold of as a defense of tradition. The fact that there are sudden, discontinuous appearances in biological phenomena no one is likely to deny, so that the *fact* of so-called mutations is one thing and the attempt to make them appear as being miraculous is quite another. To assume that neither natural selection, nor any other understandable cause, is to be credited with the appearance of mutants, is to give over science to whim and the orderliness of Nature to caprice. No really scientific mind can believe that mutants leap into existence, full-formed and panoplied, like Pallas-Athene from the head of Zeus, caused only by the decree of a god. It is much more reasonable to believe that they occur as occur landslides, where the slow undermining influences of a river make manifest its work by a sudden crisis. Every chemist who, with burette, beaker, and indicator, has estimated a substance volumetrically, is fully aware of the fact that chemistry is flooded with such sudden, apparently discontinuous, jumps. To suggest to a chemist that his suddenly appearing colors represent discontinuous creations would be to make him smile at such mental crudity. *Natura non facit saltum* is a permanent part of the chemist's creed. Physiological chemistry is rapidly proving that every part of every organism is correlated with every other part through the action of what Starling has called hormones. The thyroids, parathyroids, thymus, adrenals, testes, ovaries, hypophysis, etc., act and react on all parts of the body, by their internal secretions, in such a manner as to weave the entire being into a continuous whole. The digestion, too, is controlled by chemical hormones. They leave no room for the possibility of any profound mutation. As one physiologist declares: "The essential unity of the organism is not only fatal to the whole theory of unit characters, but it is an insuperable objection to the theory that evolution has been by jumps. The organism is a finely adjusted mechanism of a very complex kind; it seems impossible to a physiologist that one can cause a sudden large change in any part of it and have it continue to function; it is as incredible as if one should remove one of the wheels of a watch, replace it by a larger one, and expect the watch to continue to run."[37] That there are what appear to be mutations is a certainty. When secondary sexual characters appear they are due to the action within the organism of a special hormone, probably protein in nature, acting on other chemical molecules where these characters appear, and remote from the place where the hormone is secreted, the stoppage of such hormone secretion, by parasitic invasion, results in the nonappearance of these characters, thus producing visible changes analogous to mutations. Our knowledge of mass action in chemistry makes it probable that when such hormones first appeared as a fitness they could hardly have shown any effect on the externally visible characters until their volume became sufficient to overcome the resistance of the cells to the change. On becoming visible it would seem as if the characters were newly formed, while, as a fact, the cause may have been a cumulative one covering many generations. Let any hormone become subject to long protracted parasitic attack, let its structure vary in a way to resist such parasitism, and when enough of the new molecules appeared it is evident that a "mutation" would arise. The new molecules could not produce exactly the same effects throughout the system as the old ones did. Protein and other molecules must balance each other into an almost perfect amphoteric (*i.e.* neutral) whole, for in the circulation of the higher animals deviation means death. Here at least all changes must be molecular and gradual.

Huxley, Darwin's great champion, looking beyond the superficial aspects of natural selection, foresaw a coming day when evolutionists would be forced to go deeper into material facts and explain selection by the molecule. He says: "I conceive that both hereditary transmission and adaptation need to be analyzed into their constituent conditions by the further application of the doctrine of the struggle for existence. It is a probable hypothesis that what the world is to organisms in general, each organism is to the molecules of which it is composed. Multitudes of these having diverse tendencies are competing with one another for opportunity to exist and multiply, and the organism as a whole is as much the product of the molecules which are victorious as the fauna or flora of a country is the product of the victorious organic beings in it. On this hypothesis, hereditary transmission is the result of the victory of particular molecules contained in the impregnated germ. Adaptation to conditions is the result of the favoring of the multiplication of those molecules whose organization tendencies are most in harmony with such conditions."[38] This quotation was first written when Roux's theory of the struggle of the parts was being considered by evolutionists. While we can see that there is less importance to be placed on the shiftings of molecular equilibrium as these favor, from time to time, the production of greater quantities of one kind of molecule at one time and of another kind at a different time, we now believe that it is quite a different cause that is at work selecting molecules. Had Huxley lived long enough to have realized the intensity, persistence, extent, and antiquity of the parasitic struggle for molecules that are, to them, assimilable, he would have better understood the real nature of the bearing which he saw molecules must have upon natural selection. He knew nothing of precipitins, of anaphylaxis, or of the crystallographic continuity that runs from molecule to molecule in correlation with the morphological variations that exist between species and species. He did not know how strangely parallel the correspondence is between the distributions of all sporozoan parasites and the classification of their respective hosts. Parasite is related to parasite, phylogenetically, as host is related to host. They parallel each other's distribution in time and extent of variation. He did not know how curiously the respective chemotactic proclivities of the parasites paralleled the evolution of the molecules that go to make up vertebrate tissues. Some parasites have chosen muscle tissue, some blood cells, some the cells of special organs, while the probable progenitors of all show evidences of having started in the gut and branched off in their affinities toward the other tissues. The malarial parasite, for instance, in one of its phases can now only live on a vertebrate blood-cell, but its evolution is traceable back to the sporo-

zoan parasites of the epithelial cells of the guts of more primitive vertebrates. Huxley did not know that at every step of evolution, in organisms of every kind, each variation to a new organism meant a similar sort of deviation in the molecules of that organism. Had he lived long enough to have known of these facts he would, most likely, have been quick to see their bearing upon his expressed belief that molecules must be better understood in order to understand adaptations and heredity. He would have seen that something must be choosing new types of molecules and causing old types to gradually disappear, otherwise, why the grading of precipitins, why the specificity of alien proteins in anaphylaxis, and why the gradual and steady shading of protein crystal forms away from each other as grades the organisms? We know of nothing but parasites that attack protein molecules rendering them, when overattractive, unfit and dangerous possessions for their producers. We know of nothing but parasites that could possibly have kept up the slow, never ceasing, gradual picking out for survival of adapted protein molecules. Precipitins and hemoglobins appear to demonstrate that such selecting has occurred. We know of nothing other than parasites that could possibly supply selection value to fit variations in protein molecules. We know of nothing other than parasites that parallel with destructive activity the phylogenetic changes that have actually taken place in all higher organisms. The results which are demonstrable as existing are exactly the kinds of results that we should reasonably expect to follow countless generations of parasitic selection. We have substantial reasons for believing that there actually did occur countless generations of just such selecting. What is still more startling is the now well-known fact that the precipitin reaction, like the anaphylaxis reaction, is *an immunity reaction against all parasitic diseases.* Precipitins are produced wherever and whenever an animal is diseased. When the germs of typhoid fever invade the body their proteins produce within the victim's circulation precipitins for typhoid germs. Whatever the kind of germ that attacks the body, precipitins for that particular kind of germ are there and then produced.[39] The sole benefit to any organism that any person is able to suggest, as coming from the "immunity reaction" in which such precipitins are produced, is that of protection against that disease. Precipitin formation is a first step in the direction of acquired immunity. The precipitin reaction is, evidently, as old as disease and as universal as disease. It tells at one and the same time of universal resistance to disease and of the way in which the protein molecules of every kind of organism shade into each other. The protein shadings which, as we have seen, mark the path of evolution, along which every organism has traveled, *are shadings indicative of disease.* The path of organic evolution in being thus mapped out, everywhere, by a reaction that is distinctly and specifically a disease reaction would appear to be the past path of disease. The corelationship is pronounced and to all appearances unequivocal. At every point where species show kinship with other species and genera with other genera the precipitin reaction—*the reaction of disease*—is always present. It tells the double tale of parasitism and of progress and of the survival of proteins sufficiently fit to resist parasitic attacks on the one side and host protecting, parasite destroying devices on the other. It shows, too, the successive overcomings of such fitnesses by new variations, first in the host and then in the parasite, so as to keep up a perpetual pendulum swing of readaptations.

DIFFERENTIATION OF THE ERYTHEMA OF SCARLET FEVER AND THAT OF GERMAN MEASLES. DIAGNOSIS.*

By S. DANA HUBBARD, M.D.,

NEW YORK.

CHIEF, SECTION CONTAGIOUS DISEASES, N. Y. DEPT. OF HEALTH.

The difficulty of accurately diagnosing the onset of either of these two diseases is quickly recognized by those who are daily experiencing this undertaking. At present there is an unusual number of cases of both very mild scarlet fever and German measles. Adding to this unpleasantness we have several institutions where both German measles and measles are appearing at the same time. In my personal experience there is no condition which so indelibly impresses itself upon the diagnostician as his weakness in these trying moments when time is all-important. I admit, if given time to fully develop, the accuracy of the most casual diagnosis is often beyond question, but where the case can be seen only once and where it demands immediate segregation or removal the task is by no means a pleasing one.

The multiform difficulties are not always recognized by the profession or the family in their desire

*Read before the Section on Pediatrics, New York Academy of Medicine, March 13, 1913.

to "get the case" away from the home or the doctor to get the patient out of his consulting room. The removal to an observation ward would no doubt be a speedy solution but where is the ward? Owing to the limited quarters provided for the true cases special provision is impossible for these. First of all I would ask the members of the profession to relegate *scarlatina* as a descriptive term for something approaching scarlet fever or very mild scarlet fever to oblivion, as frequently by use of such a phrase the family is lured into false hope and deceptive conditions and the little patient is often permitted liberties which reflect unfavorably not only on the patient but on those exposed.

Scarlet fever in its onset can, in my opinion, assume more disguises than can almost any one other disease, presenting oftentimes a wide range of conditions with many differing clinical pictures. There are also many clinical conditions which more or less closely resemble the onset of scarlet fever. The very multiplicity of conditions should mark this disease for special consideration above all others. Therefore when called to observe a child with a rash we should ever be alert and have prominently in our mind this one disease. I have seen cases with sore throats, in which the initial culture had been negative, which were observed for a period of twenty-one days and in which no rash was observed by either parent or physician, yet they gave evidences of desquamation. It is an invariable rule in the Department of Health to have inspectors follow up cases of negative diphtheria to see if they do not peel in a few weeks' time. It is a rule that is well worth while and gives good results. What unspeakable dangers have been given free rein? How many cases similarly escape observation and detection, particularly if there is no peeling, in the very mild cases of scarlet fever?

I would that I could say: "Well, the mild cases do not amount to much anyway; they are so attenuated that they do not do much damage," but such is not the case. I have seen very severe scarlet fever follow very mild cases in a family, and in certain tenements it is not unusual to see at the onset of the epidemic several mild cases followed by very severe ones. It is my invariable rule never to dismiss any rash in a child until it has had at least forty-eight hours of development, unless its associated clinical symptoms make the diagnosis clear. A mild scarlet fever unrecognized and untreated is most often the very commencement of an epidemic; it is frequently the cause of lesions in the patient which last throughout life, deforming and disfiguring. These might have been so easily avoided. Their avoidance meant much not only to the patient but also to the community.

Classical scarlet fever is ushered in with a sudden and often unexplainable vomiting or nausea. The child is weakened and prefers to rest. Headache is often complained of. Sore throat, a stitch-like sensation on swallowing, is of early occurrence. Faucial redness is apparent. The pulse is quickened markedly and the tension is high. The tongue looks as if it were coated with skimmed milk. The glands in the neck quickly enlarge and are tender on pressure. A general erythema, punctate, finely macular, and of a bright scarlet hue (pink), soon appears and rapidly spreads over the entire frame. About the margin of the nose and mouth there is a paleness (the scarlet mask) almost positive in its clinical significance. In a few days the tongue exfoliates some of its coating, the tiny papillæ enlarge and protrude through the coating and the typical "strawberry tongue" with its almost positive clinical significance appears. The tongue is clear of coating on borders and tip and is of deep red color. With such a picture, regular and prominent, scarlet fever is positively simple to comprehend. But do all cases appear so well outlined? No! they do not. I sincerely wish, yes, a thousand times wish, that they did. These symptoms vary in degree and vary in sequence and in some do not appear at all.

Our natures differ. Some express themselves quickly while others as readily do not. Individual symptoms are variable. The degree of intensity is also variable and at times confusing. With this considered it is but small wonder that it is difficult to recognize scarlet fever in its onset. Scarlet fever in certain epidemics will assume one rôle and in another epidemic or locality will assume another rôle, which adds to the confusion not a little. This degree of variability has led to conditions which I have mentioned above, and which result in the failure to recognize this disease early.

Following the advice of that venerable medical philosopher, Fordyce Barker, the consideration of scarlet fever bids one take heed of one of his special truisms, "Young man, if you cannot do good, be sure not to do harm." Therefore in the consideration of scarlet fever in its onset let the observer at once recognize the difficulty of his task and gird himself accordingly, caution and patience being his only key. The rash of scarlet fever concerns us most in our diagnostic work, but he who makes a positive diagnosis on this one symptom alone is going to fail more often than he is going to succeed. The general picture must be carefully studied and the facts gleaned must be sifted until by absolute exclusion an accurate diagnosis is determined. The rash of scarlet fever may be intense or it may be faint. It may be universal in distribution or it may be localized. It may be smooth or it may be uneven. It may be uniform in distribution or in groups. It may be erythematous or it may be ecchymotic. It may last for a few hours or it may last for a week or more. The dermal evidence of scarlet fever is in the nature of a dermatitis. The rash is sometimes distributed so as to make the skin appear as if mottled, not true mottling as generally understood but an eruption in patches of variable size and outline and most often seen on the extremities and trunk, never on the face. In these cases there is as a rule more prominence to other clinical symptoms which aids one in the recognition of this disease. I have never observed the rash of scarlet fever to disappear quickly. It as a rule appears quickly but gradually subsides. In fact the unusually quick appearance is often an aid in recognizing this disease. The exanthem springs from individual foci which in a short time run into others in their area and this commingling with the swelling of the skin gives the dermal lesion the characteristic uniform generalized distribution and the color of a scarlet red, as if the skin had been overheated or burned by scalding water. At certain times and in some cases papules develop, these later forming tiny vesicles (miliaria).

The scarlet fever rash is associated with an itching which at times is very intense and is generally most intense in the areas which the malaria develops. The tiny individual focus is a point about the size of a small pinhead with light red coloring. The points are regular in size and are arranged at about equal intervals. When numerous they form

the characteristic picture. The skin soon swells, the foci commingle, and the dermal coloring is uniform like a blush. With many fine points appearing on a pallid skin the picture of the onset is indeed unique and by reason of the short period at which this stage continues it is most frequently non-recognizable. The rash of scarlet fever never starts to desquamate on the day of subsidence. If irritants are applied, as frequently occurs about the throat, where skin is tender and thin, it will peel early, but this is incident to the treatment and not the course of the malady. The starting of peeling about the margin of the finger nails and the appearance of fine opalescent white pin point areas on the derma is rather indicative of scarlet fever desquamation. Several of these small areas come together and the skin is lifted as it were, the denuded part being easily torn away in small patches or sheets. As a rule scarlet fever starts to peel about the twelfth to the twenty-fourth day of the disease and it generally takes from thirty-five to fifty days to complete the work. The peeling of scarlet fever is not characteristic. It is an error to think so: pemphigus, dermatitis exfoliativa, erythema multiformae, and medicinal eruptions frequently simulate scarlet fever in its desquamation. The peeling may at times be so superficial as to appear furfuraceous, or there may be such a slight amount of exfoliation as to make the skin feel finely granular and roughened with no regular casting off of the top layer. I think that in those cases in which there is no peeling by the twenty-first day of the disease the diagnosis was in all probability erroneous.

Scarlet fever, therefore, with all of its cardinal symptoms following in fairly regular sequence and prominence, may be said to be not ordinarily difficult to recognize; but in the light of twenty years' experience, intimately associated with cases in all stations of life, this regularity is the exception rather than the rule with this disease. Scarlet fever becomes classical in my experience only when it is fully developed, and therefore I say most candidly and with all sincerity that a formally expressed opinion should never be given until it is assisted by such careful observation and development. There is no reason for the non-recognition of this disease. In hospital work, without wards where the cases may be kept under observation for a sufficient time, and in work in which patients are found in temporary places from which they must be quickly removed, the action of the physician should be most guarded and the opinions should be most reserved.

German Measles.—Up to a few years ago the medical profession paid but slight attention to this disease, probably because it was the mildest of the exanthemata and had but slight interest "of itself," except possibly from the viewpoint of an accurate diagnosis. The misadventures following its non-recognition evidently led to its more careful study. This disease has for years been one of the infectious ones, the report of which has been required by the Department of Health, but up to 1904 we do not find that it was reported. Then special attention was taken, and there were reported 1,075 cases, and for the years following there have been reported the following number of cases: 1905, 153; 1906, 360; 1907, 785; 1908, 544; 1909, 270; 1910, 871; 1911, 758; 1912, 697. This year there has been quite an epidemic, as is shown by the reports for January, 226 cases reported; February, 205 cases, and up to date 420 for March, making 851 cases for the year 1913.

The average medical attendant in private practice is not often called in nor does he see many of these cases until the rash is well out, and unfortunately, owing to their short tenure and non-recognition at the initial visit, the memory picture with its hazy tinting has not left a very clear impression on his mind. This I attribute more often to the failure to recognize this disease at the commencement of an outbreak in new localities. Also most often it is classified as a mild scarlet fever and justifiably so, I might add more safely than is the rule.

German measles will run its course in from a week to ten days; by this time with careful, competent observation it should be easy of recognition. I cannot impress, however, too strongly in this disease the care that should guard every opinion expressed before it is fully confirmed by lengthy observation. The avoidance of an error is most necessary and scarlet fever should always be prominent in our mind. The care of the patient and the protection of others from exposure while the disease is developing should be as rigid as if the diagnosis was positively scarlet fever.

A characteristic case of German measles develops something like the following: Children usually from 4 to 10 years of age, though no age is exempt, are the ones attacked. The child sneezed a little during the night, there was a slight dry cough at irregular intervals. The little one did not eat its supper with relish; it slept well but the next morning one noticed that the face was flushed, the tint deepest about the cheeks, near the nose, and particularly about the upper and lower lip. The redness seemed to consist of minute pinkish spots, distinct enough to be observed easily with the eye. To the touch they were not elevated. The skin felt as if fine grains were just under the surface. The little spots ran together forming a blush and as they appeared at other parts they behaved likewise until the face, neck, arms, and body were covered. The rash was fading on the face about the time it reached the lower part of the torso. It took about twenty-four hours to cover the entire body. The patient in proportion to the amount of rash present did not appear as ill as one would have reason to expect. He appeared fairly comfortable and looked as if he was wondering why he caused so much concern. The temperature may be normal, it may be 99° F., or it may rise at most to 100° F.

The sublingual and posterior cervical chain of lymphatics appear somewhat enlarged, they are soft to the touch and are not very sensitive. These glandular chains are very characteristic; they appear early, and should be sought for as the first confirmatory symptom. They are rather uniformly enlarged and are just to the outer edge of the trapezius muscle. They feel like a small string of beads. The conjunctivæ are but slightly, if at all, affected. There is at times some sensitiveness to light. The mucous membrane does not appear affected except on the soft palate where at times small petechial areas of redness are found (Forscheimer's spots) in little masses. There may be subjectively a severely painful throat but objectively there is practically nothing to account for the same. This angina is not uncommon in this disease. In some children, particularly those of a nervous temperament, there may be observed chilliness, loss of appetite, restlessness, thirst, etc., usually in proportion to the amount of temperature present.

During the first day the rash fades and next day

it is gone. The patient is bright, mentally contented, and bodily comfortable. In three or four days there is a fine furfuraceous desquamation which feels finely granular to the touch; it may, however, be so slight as not to be apparent either to the sight or touch. In some of the unusual cases, however, the peeling is quite extensive and closely resembles that of scarlet fever. In the vast majority of cases of German measles, however, the desquamation is slight, it is furfuraceous, and within a week every vestige of the disease disappears and practically without any treatment. German measles is claimed by some to be contagious; it may be so, but to my mind it is like all other diseases of which the cause is known, simply infectious. The infectious material may be more easily carried and be more tenacious than other forms, but contact with a patient is, to my mind, the only way the disease is disseminated. Light and air quickly destroy the infection. Household cleaning, therefore, with ventilation, is ample for cleansing apartments in place of gas fumigation. One-half pound of washing soda in three gallons of warm water applied with energy will clean a place much more satisfactorily than will our modern sealing and fumigating.

German measles occurs as a rule in epidemics and is much less infectious than is ordinary measles. I have never observed a case of German measles in infants under one year of age. One attack of this disease as a rule confers immunity, though there are those who claim it may occur a number of times in the same person. I have seen several persons fairly reliable who claim to have had it under competent observation twice. I have never seen a case of this disease of more than ordinary mildness —though there are those who state that it at times becomes very severe. I have never seen any sequlæ of unpleasant character follow this disease. German measles is infectious from onset to termination of convalescence. The infectious material is probably carried by the material discharged from the nose and mouth. The period of incubation is variable. Usually from five days to surely not more than four weeks. (This is the longest time I have found recorded and I doubt it myself.) Where observation has been practical the period of incubation was found to be from fourteen to eighteen days. The stage of invasion lasts from a few hours to about two days. Usually it is very short and the first thing observed is the presence of the rash on the face. Occasionally there is a slight angina but as has been said the painful throat is out of proportion to the amount of objective manifestations present. In cases of German measles in which the rash is intense it will be found on the palms and soles, and it will be followed by rather profuse exfoliation. The individual lesions of German measles are of a size between the points of scarlet fever and the macules of measles. The coloring of German measles is not a vivid red as is the pink of scarlet fever and yet not of that purplish red distinctive of measles. Seen in bright sunlight it has a violaceous hue. The rash of German measles as it appears is a slightly visible light reddish macule discreetly located and generally distributed. The lesions disappear on gentle pressure and are but very slightly, if at all, elevated. They feel like granulations of fine material just under the skin. At the height of the flush circumscribed darker colored macules develop, giving a rather dark red to a fiery red coloring of the derma. The tiny macules are isolated, they are about the size of a small pinhead, but may at times appear to be as large as a small bean. Between the macules may be observed distended capillaries. The macules disappear on pressure but the coloring almost instantly reappears on removing same. The macules are of two varieties: in one the spot is perfectly formed at the time of appearance, sharply limited, with irregular borders and obtuse or angular surfaces. One macule does not touch another during the entire course regardless of the severity or intensity of the rash. They become numerous and are very close together but are individualized. In the other variety of German measles the macules appear as red pointed with distinct outlines which may spread at the periphery and at times reach a diameter of two or three lines. The first variety is the one most commonly met with and is the morbilli form type. The second variety is the more severe form and usually has the more intense eruption and also closely resembles scarlet fever. It is almost diagnostic and a point to be kept well in mind that, no matter how intensely red the derma may appear, on close examination the rash is seen to consist of tiny red points. Glass pressure (ordinary microscope slide) will reveal the individuality of the lesions. One should press on the part until it is pale, then remove the slide quickly by sliding it off, the paleness departs, the original tiny red points reappear quickly and then the general blush resumes its former tinting. The color spreads at the periphery until the paleness has disappeared. In those cases of German measles closely resembling scarlet fever the skin is red and the macules are haloed, the halo uniting with others in the vicinity in little streaks and forming, as it were, stripes as they join. Elevation is not apparent in this class. The color of German measles is of a slightly darker tint than is the light pink tint of true scarlet fever. The rash of German measles as it fades gives a rather brownish red and then a lighter brown shading and as it disappears leaves no mottling in the derma. An itching of the skin I have never observed in German measles. The cases of German measles in which the throat has simply a diffused redness and in which there is some pain on swallowing are those which form the scarlatinal type of German measles. The desquamation of German measles is usually in proportion to the severity or intensity of the rash and the amount of overheating of the skin surface.

Regarding cases of exanthematous diseases which physicians report as being without a rash, I invariably observe these for confirmatory evidence and if such cases fail to peel by the twenty-first day I feel, in my opinion, that there is an error of diagnosis. Personally I do not believe any more in scarlet fever without a rash than I believe in smallpox without a rash or chickenpox without a rash. There is no one disease whose control and abolition would confer a greater or more lasting benefit upon mankind than scarlet fever. Of all the world's scourges of both modern and ancient times there is none that can claim the ravages through death and deformity that are wrought by scarlet fever.

For the purpose of argument let us consider scarlet fever as being due to a germ. This germ is probably carried by persons who act as "carriers," by mild unrecognized cases, and by intermediary hosts (fomites), and our precaution, if we would control scarlet fever, has got to be through control of these factors. Prompt recognition, practicable segregation, careful and continued isolation, prompt and thorough disinfection, with attention to "car-

riers," will, in my humble opinion, in a remarkably short time control this one great pest.

RECAPITULATION.

Scarlet Fever	*German Measles*
More or less severe constitutional symptoms.	Very slight constitutional symptoms.
The severity and intensity of the rash is in direct proportion to the constitutional manifestations.	The severity and intensity of the rash are in inverse proportion to the constitutional symptoms.
Enlarged glands, usually following onset and evidence of sepsis.	Enlarged post-cervical chain of glands like a string of beads early in onset.
Glands swollen and tender.	Glands enlarged, soft, and not tender.
Confluent scarlet (pink) rash.	Non-confluent, dark-red (violaceous) rash.
Rash punctate.	Rash macular.
Onset sudden and more or less severe.	Onset sudden but not severe
Tongue, milk-coated; later, "strawberry," about third day.	Not affected.
Pulse, high-tension and increased in frequency.	Not materially affected
Circumoral pallor.	Rash starts about the nose and upper and lower lips.
Vomiting.	No vomiting.
Rash appears quickly, spreads rapidly, and disappears gradually.	Rash appears in one part at a time, appears gradually at other parts, fading at place of onset. Covers body in about twenty-four hours.
Rash appears first on neck and about clavicular spaces.	Rash appears about nose and lips.
Scarlet rash fades with yellowish shading. Leaves skin more or less injected.	German measles rash fades with a brownish red, then to a light brown, and disappears, leaving no mottling of skin.
Desquamation in 12 to 24 days.	Desquamation in about 3 days.
Desquamation in sheets. Squamous scales.	Desquamation furfuraceous.
Has more or less severe sequelæ.	Has none.
Itching more or less prominent.	Not present.

143 WEST ONE-HUNDRED-AND-THIRD STREET.

OBSERVATIONS AND SUGGESTIONS REGARDING LOBAR PNEUMONIA.*

BY EDWARD E. CORNWALL, M.D.,

BROOKLYN, N. Y.

ATTENDING PHYSICIAN TO THE WILLIAMSBURGH AND NORWEGIAN HOSPITALS; CONSULTING PHYSICIAN TO THE BETHANY HOSPITAL

DURING the three months ending April 1, 1913, the writer treated in two hospitals twenty-nine cases of lobar pneumonia; these cases form a continuous series, being all of the cases of that disease treated by him in that period in those hospitals. The ages of these patients were respectively: 3, 3, 3, 6, 6, 9, 10, 10, 19, 21, 21, 22, 22, 23, 26, 30, 30, 30, 34, 34, 35, 36, 38, 38, 40, 41, 44, 52, and 57 years. The lobes affected were as follows: In thirteen cases the left lower lobe; in seven, the right lower lobe; in two, the right upper lobe; in one, the left upper lobe; in one, the right middle lobe; in three, both lower lobes, and in two, both left lobes.

The temperature in five cases rose to 105° F. or higher; in eleven to between 104° F. and 105° F.; in ten, to between 103° F. and 104° F., and in three it did not rise above 103° F. The pulse rate in three cases rose to 160 or more; in four, to between 150 and 160; in three, to between 140 and 150; in six, to between 130 and 140; in nine, to between 120 and 130, and in four it did not rise above 120. The respiration rate rose in five cases to between 60 and 70; in five, to between 50 and 60; in thirteen, to between 40 and 50, and in six it did not rise above 40.

Defervescence took place in sixteen cases by lysis, and in nine by crisis. The average time of defervescence in the cases which showed lysis was 7.7 days from the beginning of the disease, and in those which showed crises, 8.2 days, the variations being between four and fourteen days. There was delayed resolution in four cases, with reinfection in two. In two cases empyema developed. In two cases there was pleurisy with effusion. In one case pericarditis with effusion was present. Two cases developed following an operation for appendicitis, one developed during convalescence from typhoid fever, and one during convalescence from rheumatic fever.

In this series of twenty-nine consecutive cases of lobar pneumonia only one death occurred. The patient who died was a boy of nine years, who defervesced by lysis on the seventh day, and died suddenly the following day, from what cause the writer was not able to discover.

The cases above reported are, of course, too few in number to form a basis on which to build conclusions, and the writer has not presented them for that purpose, but for the purpose of providing a text, a suggestive text, for a few topical remarks on the subject of lobar pneumonia.

The Toxemias of Pneumonia.—The toxins which most commonly make trouble in pneumonia can be divided into three classes: the specific toxin; autotoxins, including those manufactured in the alimentary tract; and pharmaceutical toxins. The specific toxin which is derived from the pneumococcus in the blood does not seem to be regularly a factor of grave pathological importance, though occasionally it may be so. It is an endotoxin, and apparently does not get into the blood stream in dangerous quantity if the leucocytes are active in the performance of their protective function. It is not regularly and habitually a serious disturber of the circulation in the sense that the toxin of diphtheria is such. In a certain proportion of cases, however, the disease does seem to overwhelm the patient, and that sometimes early in its course, in a manner which suggests the presence of a severe specific toxemia. The writer has seen a few such cases. But in none of the series above reported, though high fever and rapid pulse, and even delirium, were unusually prevalent, did vasomotor paralysis appear as a cause of cardiac failure; the circulatory disturbances which were observed could all be accounted for by the mechanical conditions present and by the state of the myocardium.

The autotoxins, we can readily believe, are of many kinds. The disturbances of the physiology caused by the conditions of the disease, both those due to the invasion of the pathogenic microrganism, which introduces into the blood foreign protein and makes a sudden and great demand on the body for biological and biochemical protection, and those caused by a mechanical disturbance of the circulation, may justly be suspected of bringing about perversions of the internal secretions and of metabolism, with resulting changes in the regular or habitual toxic and antitoxic conditions in the blood stream and in the glands and tissues. And it can also readily be believed that the same disturbances lessen the natural resistance of the body to the toxic products of bacterial activity in the digestive tract, and also that they favor the production of such toxic products. The writer is of the opinion that the autotoxins, and particularly the toxins of intestinal origin, constitute a very important element in the mixed toxemia of pneumonia.

The pharmaceutical toxins are, of course, drugs given to the patient. Most of our drugs are poisons. The pharmacopeal alkaloids, drugs belonging to the coal tar, carbolic acid and salicylic acid groups, mercury and magnesium sulphate, all of which are

*Read before the Kings County Medical Society, April 15, 1913.

widely used in pneumonia, are familiar poisons, and even dangerous ones unless used with caution. In view of the wide diversity of opinion which obtains in the medical profession regarding the drug treatment of pneumonia, and the necessarily unripe clinical experience of a considerable proportion of those who treat cases of this disease, and, we may add, the therapeutic prejudices which are so easily and so naturally acquired and from which it is so difficult for any of us to be entirely free, we are bound to include among the toxemias which may be found in pneumonia, drug toxemias.

Of these three classes of toxins, the first, the specific toxin, is, in the present state of our knowledge, beyond our direct control; we can influence it favorably only by supporting the natural resistance of the body, and particularly by improving the hygiene and nutrition of our faithful janissaries, the leucocytes. Of the autotoxins, those formed in the alimentary canal are very largely under our control. It is possible by regulation of the diet to greatly reduce the amount of injurious bacterial activity in the alimentary tract. The third class, the pharmaceutical toxins, are entirely under our control. The proper exercise of that control, however, is not always easy, for some of these pharmaceutical toxins we know can often be used with advantage to the patient. But when we put a drug with toxic possibilities into a patient suffering from such a grave disease as lobar pneumonia, in which a very small thing may be sufficient to turn the scale, we should be reasonably sure that the advantage will be greater than the injury; and when there is any doubt we should give the patient the benefit.

The Blood Pressure in Pneumonia.—H. A. Hare in the 1912 edition of his "Practical Therapeutics," says, "Gibson in Edinburgh, and myself in this country, have shown that danger arises when the pulse rate per minute is equal to or above the blood pressure expressed in millimeters of mercury. Thus, if the pulse rate is 90 and the blood pressure 140, all is well, but if the pulse rate is 110 and the blood pressure 110 the patient is gravely ill, and needs active cardiac and vascular stimulation. If the blood pressure in millimeters of mercury falls below the pulse rate the condition is desperate."

The writer's experience does not support these conclusions of Gibson and Hare. In seventeen of the twenty-nine cases above reported, the blood pressure was taken by a sphygomanometer, along with the temperature and pulse rates, and in fifteen of the seventeen it fell below the pulse rate, yet all recovered, and in eight more the blood pressure could easily be appreciated by the finger to have fallen below the pulse rate, yet all recovered. The writer is of the opinion that the systemic blood pressure in pneumonia differs very little from the normal for the individual, as a rule, and that when it does fall this usually happens as a result of the mechanical failure of the overworked heart, and that the collapse of the circulation through specific-toxemic vasomotor paralysis, of which so much has been said of late, does not regularly belong to the disease, being an occasional occurrence and not always clearly distinguishable from collapse of the circulation due to myocardial failure. The terminal collapse of the circulation in fatal cases may not differ essentially from what happens at the end of a losing fight by a patient with any fatal cardiac disease, except that the specific toxemia is added to other habitual toxemias which are present in excess on account of the general circulatory stasis.

The Hygiene of Pneumonia.—The most important point in the hygiene of pneumonia, next to keeping the patient in bed, is to supply him with plenty of cold, fresh air. The writer will not discuss this generally accepted proposition, but he wishes to emphasize a germane point which he believes is not sufficiently regarded, viz., the necessity for protecting the patient from cold and drafts after defervescence. While his fever endures, the patient can come to no harm from exposure to cold air, in fact, is benefited by it; but after his fever has gone, and he lies weak, possibly perspiring, a reinfection of the lung or an attack of pleurisy can be induced by such exposure.

The Diet in Pneumonia.—In lobar pneumonia, as in other acute infectious diseases, the digestive organs are less active than normal, and are in a condition which can be easily disturbed by any but the most simple food. The liver is less capable than in health of performing its important and complicated functions, particularly its antitoxic function, on which unusual demands are being made. The kidneys, with reserve power lessened, are called on to eliminate an increased amount of waste and toxic material. In the condition of the heart and blood vessels indications for regulating the diet are found which are of the greatest importance. The unstable condition of the heart makes particularly dangerous disturbances due to nervous reflexes from the abdominal viscera, and especially those due to mechanical pressure from the abdominal cavity, which are caused by flatulent distention of the stomach or intestines. Abdominal distention, so dreaded in pneumonia, depends largely on indigestion and harmful bacterial activity in the intestinal contents.

The dietetic indications above suggested can be met, according to the experience of the writer, by giving, during the febrile period and for a few days after, food of a fluid, antiputrefactive character, consisting of modified milk, thin cereal gruels and fresh fruit juices, in quantities which will supply a daily ration of not more than 40 grams of protein and possess a fuel value of not more than 1,250 calories, and, in addition, full rations of the food salts required by the body. The twenty-nine cases above reported were so fed and no marked tympanites developed in any of them, nor any serious symptoms referable to the alimentary tract. Among the food salts, those of calcium call for special consideration in pneumonia. Calcium, which in certain amount is required by all the fluids and tissue of the body to maintain their healthy condition, and particularly by the muscle of the heart to enable it to contract in its best manner, and by the leucocytes to increase their functional activity, is regularly deficient in pneumonia. A condition of calcium starvation exists to a greater or less degree in this disease, which is brought about by the withdrawal of the stores of that element in the body to supply extraordinary requirements, viz.: to coagulate the fibrin in the consolidated lung, to feed the large number of new leucocytes which have made their appearance on the field of battle, and even to feed the invading pneumococci, which seize calcium in the enemy's country for their own use. Unless this calcium deficiency is made good by the addition of a sufficient quantity of that element to the diet, there is reason to believe that the patient is handicapped in his struggle with the disease. The writer has included calcium chloride in the diet of nearly all of his patients with pneumonia since his attention was called to the importance of this article of food

in pneumonia by Mitchell a year and a half ago.

The Use of Cathartics in Pneumonia.—Hippocrates, in his second *aphorism,* says: "Artificial evacuations, if they consist of such matters as should be evacuated, do good, and are well borne; but if not, the contrary." Who will deny the soundness of the teaching of this aphorism? While unnecessary or excessive catharsis may not do serious harm in many conditions, in a disease where failure and recovery are often so delicately balanced as they are in lobar pneumonia, it is quite possible that they may do so, and that they may even be fatal factors. The propriety of moving the bowels at the beginning of the disease if they have not acted within a reasonable time is unquestioned, but there seems to be no reason why this procedure should be made a violent one, thereby possibly disturbing its intestinal mucosa and impairing its resistance to the absorption of toxins; or that it should be indulged in more than is necessary; and especially to be condemned, in the writer's opinion, is the custom, so prevalent, of giving a dose of calomel followed by magnesium sulphate at the beginning or at any time in the disease. Mercury is of great value in many conditions, but the writer sees no reason why it should ever be used for the primary purpose of a cathartic and some why it should not; and magnesium sulphate is a toxin of so great cardiac depressant power, and so difficult to eliminate by the kidneys after absorption, which takes place in direct proportion to the strength of the solution, that he holds it to be a dangerous drug to use in pneumonia. The writer prefers to use, in most cases, castor oil or a vegetable cathartic at the beginning of the disease, in sufficient dose to insure a thorough but gentle evacuation, and after that, in general, to use simple enemas; and he believes that if the bowels are moved every second day that will be quite often enough, provided the patient's diet is so regulated as to minimize putrefactive and fermentative processes in the alimentary tract which are of a menacing character. At or near the time of defervescence, or at any time if the heart is in distress, he prefers not to disturb the bowels at all.

The Use of Morphine in Pneumonia.—Pain, restlessness, and sleeplessness are common symptoms in pneumonia, and it is highly desirable, especially during the early days of the disease, that they be relieved so that the patient will get such an amount of sleep that he will be able to approach the crisis of his struggle without the handicap of nervous exhaustion. For the relief of these symptoms no drugs are so efficacious, and at the same time safe, as the alkaloids of opium. The writer believes that in the early days of the disease morphine or codeine should be given in moderate doses to secure a fair amount of sleep if the patient is suffering for lack of it; and later in the disease these drugs may also be given if needed, though with caution and in very small dose, because it is undesirable to severely depress the respiration if the respiratory area is extensively encroached on, and especially is it undesirable to give opiates in any but small doses, if in addition there is circulatory failure and general pulmonary congestion. Analgesics and hypnotics other than opiates the writer does not at present employ in his treatment of pneumonia.

The Support of the Heart in Pneumonia.—The heart in pneumonia, except when the disease occurs in young children, nearly always needs direct support at some time during its course. This support consists mainly in judicious stimulation. In the aged, in alcoholics, and in those with preexisting myocardial weakness, stimulation is usually required from the beginning. In young adults with originally healthy hearts it can usually wait until signs of strain appear, but it should not be delayed too long; it is better to give help before it is needed than to withhold it until after damage has been done. In most cases, on the third or fourth day, even if no symptom of circulatory disturbance appear, it is reasonable to suppose that the right heart is getting tired and would be benefited by a gentle stimulant. The amount of stimulation should, of course, be regulated by the requirements of the circulation, and the best guide to those requirements is the condition of the right ventricle, on which rests the burden of overcoming an obstruction in the pulmonary circulation. The most distinctive signs of failure of the right ventricle are: increase to the right of the area of deep cardiac dullness, and diminution in intensity of the closure sound of the pulmonary valves, and, in addition, when failure is pronounced, cyanosis and other evidence of venous stasis. When the failure of the heart is due to vasomotor paralysis there is apt to be a grayish pallor instead of cyanosis. While stimulation of the heart is very often called for, and sometimes a large amount of it, special care should be taken not to exhaust the heart by the excessive use of stimulating drugs. Complete relief of the cardiac symptoms when extreme should not always be attempted; it is often sufficient for our purpose if we can keep the patient from dying for a few hours or days, until his disease has run its course; and it is easy to precipitate a circulatory collapse by over-stimulation. The temptation, however, is very great to use extreme, even desperate measures of stimulation, when weakness and irregularity of the pulse appear before the crisis, with a steadily increasing pulse rate, a dilating right heart, an inaudible pulmonary second sound, and moist râles all over the lungs. But even of such cases the writer believes that more will be saved by keeping the stimulation of the heart within conservative limits than by yielding to desperate impulses. One method of treatment which has been recommended for cases of extreme right heart dilatation, viz., venesection, appeals strongly to the writer, though he has used it only once, and then with success. Among the numerous drugs which are used to stimulate the heart in pneumonia there is considerable choice. The writer has found the best results from the judicious use of strychnine and strophanthus as primary heart stimulants, with caffeine, digitalin, and aromatic spirits of ammonia as secondary or reserve stimulants.

In closing these few topical remarks on lobar pneumonia, the writer would like to repeat and emphasize the following suggestions regarding the treatment of that disease: (1) Give the patient plenty of fresh, cold air, but after defervescence protect him carefully from being chilled. (2) Keep down the production of toxins in his intestines, which form a very important element in the toxemias of pneumonia, by giving him a fluid, antiputrefactive diet, supplying not more than 40 grams of protein daily, and possessing a fuel value of not more than 1,250 calories. Do not hesitate to give much less than the above quantities should abdominal symptoms appear. (3) Include in his diet sufficient quantities of the salts needed by the body, particularly the salts of calcium. (4) Do not delay too long stimulation of his heart; regulate the

amount of the stimulation by the capacity of his heart muscle to respond as well as by the requirements of his circulation. (5) Do not move his bowels unless they need it, which they will not be apt to do oftener than once in two days, if his diet is regulated so as to minimize injurious bacterial activity in his intestines, and let the methods used to move them be gentle.

OBSESSIONS IN MEDICINE.

By BEVERLEY ROBINSON, M.D.,

NEW YORK.

Presumably these have always existed to a greater or less degree—and yet, it seems to me, so far as my own life and experience are concerned, they exist to-day to a greater extent than heretofore. If it be true, why is it? Two reasons may be given; no doubt there are others.

The first is, exaggerated specialism; the second, an undue estimate of science, passing though it be, as opposed to wise empiricism—*i.e.*, the experience of decades, not to say centuries.

In every field we should have experts, namely, men of highest attainment in their special field of knowledge. While this is true, their number should be limited, partly because we should recognize peculiar fitness only when based upon excellent training and much later work and experience. With this we must demand very great consideration for the wider knowledge and experience of the all-around physician. Common sense in both must be considered a very important additional quality. This common sense means really sound judgment. If this be present, both men—specialist and general physician—will regard the patient as a whole, and hence will advise in accord with this idea, so essential to the ultimate well-being of the patient.

As to science, as it is termed, what is it in fact, in medicine? To-day it is and to-morrow is not. It is ever changing, at least much of it. Illustrations without number could be given to prove it. It is only a few years since that the revelation under the microscope of the tubercle bacillus pointed to the disease with unerring certainty and not only that, but in it was the cause—indeed, finally, the only one. Now, not a few think of the tubercle bacillus as a scavenger, not a direct and efficient cause. Again, presuming it is found, are we to attach the same importance to it invariably? Evidently not. In some instances it may have an absolutely similar appearance as in others, but it has relatively very little virulence. This is shown first by the results of inoculations in animals, especially guinea pigs; secondly, by reason of the manner and duration of cure, if there be cure. In certain cases we know, once the disease is firmly established, cure does not take place. The germ is virulent and the soil in which the germ is planted is of the sort to support and propagate this virulence.

Where do we find obsessions which are familiar to all at the present time? One is, and, to my mind, greatly to be deplored, the exaggerated and widespread notion of the marked contagiousness of consumption, *i.e.*, pulmonary tuberculosis. This prevailing conviction, which extends among doctors and laity, causes great anxiety and harm, and moreover is not true. Only under certain circumstances is pulmonary tuberculosis carried from one person to another—usually in the advanced stages—and almost invariably it may be obviated by certain and a few careful observances and by intelligent, simple treatment.

Again, many doctors, and many people, are obsessed with the idea that rest, fresh air, good food, will cure the disease and that drugs are relatively inert or useless. The result is that in one, not to say several, of our well known sanatoria, very little, or no attention, is paid to the use of drugs. What a lamentable error! Is all the work and wisdom of men who preceded us to go for naught? Are creosote, the hypophosphites, cod-liver oil, worthless and simply to be thrown aside? I do not believe it, and I am sure I state the truth. They have their time, their place, their indications, and should be used advisedly and to the great advantage of many.

Immediate operations for appendicitis are now urged at home and abroad, and by very many of the best surgeons and physicians. I protest against any such rule of practice because I believe it to be woefully wrong. I have watched the trend of practice for many years and have been a frequenter of the dead house in large hospitals. Of course patients did die and would die because of general peritonitis, due to perforation, and when not operated upon. As a fact, patients not infrequently die subsequent to, and because of operation, who, if managed sanely and by the old-time practitioner, would recover. I do *not* affirm that the cure in bad cases, and by these I mean perforation and general peritonitis, or, indeed, where it is shut off and limited by adhesions, would be as rapid if it occurred, but I do mean to affirm it would be quite as safe and sure. I am quite aware that this statement, if considered and answered, will meet a storm of contrary judgment, but I state my belief all the same, unwaveringly. One method used nowadays, before operation, I deplore, and that is the use of the ice-bag. It may diminish pain, but little more than alcoholic applications locally, and codeine internally, and surely, to my mind, it prevents the re-establishment of circulation in the appendix and adjacent colon, which is usually implicated in the disease. I still believe, and despite all manner of invective against purgatives, in threatened or declared appendicitis, that a dose of castor oil rarely does harm. The amount of increased peristalsis caused by it may, indeed, occasionally determine a rupture of the appendix a little sooner than it would otherwise occur, but in the majority of cases it will help prevent an unnecessary operation. However, in order to avoid the minimum additional risk of which I speak, and out of regard for a widespread obsession, as I believe, I would be content very frequently with large and repeated oily enemata.

Another obsession in medicine is the idea that little can be done to reduce the mortality of pneumonia. Nothing is more foolish, more wrong-headed. If the patient is put to bed as soon as threatened, and creosote inhalations started and other judicious medical treatment employed, he will recover, provided he is not already much handicapped by previous disease, or by reason of great weakness, or old age, or because the poison is very virulent.

While I believe firmly in the value of warm creosote inhalations from the croup kettle, I acknowledge that it is difficult to have it carried out when most valuable, namely in the initial stage of the attack, by reason of the lack of confidence in its utility on the part of the patients and physicians, and, also, because of the unpleasant odor of creosote

to many persons. This latter objection can be in a measure overcome by the addition of compound tincture of benzoin to the water in which the creosote is also vaporized.

TUMOR OF OMENTUM WITH TWIST OF PEDICLE, GIVING SYMPTOMS OF ACUTE APPENDICITIS.

By C. LEGIARDI-LAURA, M.D.,

NEW YORK.

Solid tumors of the omentum are of very rare occurrence, and many tumors at first described as omental were later found to be of intestinal origin with secondary omental connection.

These pseudo-omental tumors are differentiated from the true omental tumors by the intimate connection of the former with the walls of the stomach or intestine, and, therefore, not being separable, unless through a resection of a portion of the gastric or intestinal wall.

The usual site of a true omental tumor, according to the authors, is the mesogastrium and the symptom complex is very obscure; especially so if the tumor has contracted adhesions and lost mobility.

Going over the medical literature of omental tumors I was not able to find a single case occurring with twist of its pedicle. This fact, together with a rather peculiar symptomatology, has induced me to report the following case:

Mr. L. B., 48 years, tailor. Never had any illness of importance, except repeated acute tonsilitis, and never any abdominal complaint except a habitual constipation of mild character. On February 26, 1913, he had a friendly tussle with another man, in which his body was briskly rotated and strong contraction of his abdominal muscles occurred. A few hours afterward he began to complain of a pain in the lower right quadrant of his abdomen. The next day the pain was much increased and at night the patient felt feverish. I was called in to see him on the third day of his illness. He complained of sharp pain over McBurney's point, radiating to the front of the abdomen. The examining hand found at McBurney's point a tender nonmovable mass, about the size of a small orange, and apparently neither smooth nor completely traceable. Temperature was 101° F., pulse 110, respiration 28. He was admitted the next day to the Washington Square Hospital, where I immediately operated on him for supposed appendical abscess.

Upon opening the abdominal cavity by the pararectal route a mass presented itself, oval in form, about the size of a goose egg, congested, and of fleshy consistency. I found it very easy to free the mass from slight, recently formed adhesions and bring it out of the incision. It then appeared to be a tumor on the anterior aspect of the great omentum and near the free border and connected with the omentum by a thin vascular pedicle, which was twisted.

The pedicle was apparently the only source of blood supply for the tumor. The omentum itself appeared normal except for a slight thickness all around the tumor which it embedded, and some recently formed adhesions to the contignous structures. There was no difficulty in ligating the pedicle and removing the tumor.

Right beneath the omentum a rather large but otherwise healthy looking appendix was found; it was amputated by the usual method.

The patient left the hospital thirteen days after the operation. Gross and microscopical examination of the tumor showed it to be a lipoma with a well-developed fibrous capsule. Two small hemorrhagic infarcts into its substance revealed the beginning effects of the twisting.

A somewhat similar case clinically, though not pathologically, was reported by Cullen of Johns Hopkins Hospital, where symptoms of acute appendicitis developed after a sudden rotation of the body, and were caused by a torsion of the omentum itself.

In my case, the location of the tumor on the anterior aspect of the omentum from which alone it derived its blood supply through the omental pedicle, and the absence of important adhesions to any portion of the intestine, prove that the tumor was in the strict sense of omental origin. Again, its fixation by recent adhesions, its location near the appendix, the acute attack of pain caused by the twisting, and an accompanying elevation of temperature explain the clinical peculiarity of the case with its resemblance to appendicitis.

135 Macdougal Street.

The Clinical Diagnosis of Latent Hereditary Syphilis.—A. Goldreich calls attention to the importance of this subject, inasmuch as in one-third of all cases of latent inherited syphilis the Wassermann reaction is negative. The most distinctive sign is enlargement of the cubital lymph nodes. These were palpable in 104 out of 130 of the author's cases of latent syphilis. In non-luetic infants these were palpable in from 15 to 17 per cent. of the cases.—*Zeitschrift für Kinderheilkunde.*

Immunity of the White Rat to the Diphtheria Toxin.—A. Pettit reported before the Société de Biologie, June 7, the results of his investigations on this subject. He found that this animal possesses a resistance to the diphtheria toxin to an extent greater than any other mammal. Whereas a dose equal to one fifteen-thousandth of the body weight kills in less than forty-eight hours, it is necessary to give an amount exceeding one one-hundredth of the body weight to accomplish this result in the rat. This resistance is not dependent upon the antitoxic properties of the blood serum or upon the power of leucocytosis, but is the result of the natural immunity of the bodily cells.—*Gazette des Hopitaux.*

High Blood-Pressure.—W. Edgecombe presents the following summary of his experiences: The measurement of blood-pressure by the mercurial manometer is, on the whole, reliable, and furnishes a useful clinical guide. There is a condition of "functional" or "neurotic" high blood-pressure not due to arteriosclerosis and distinguishable from hyperpiesis. In the majority of cases of "functional" high blood-pressure, direct treatment is unnecessary and may be harmful. "Functional" high blood-pressure does not readily lead to arteriosclerosis. The significance of high blood-pressure as a symptom is less serious than is usually supposed. The treatment of early cases of hyperpiesis is imperative and is usually satisfactory. Spa treatment gives the best results. The treatment of developed arteriosclerosis is unsatisfactory and should be mainly by general measures and periodic spa treatment rather than by drugs. Excess of treatment may be harmful as liable to accelerate cardiac defeat. The prognosis in cases of high blood-pressure is less gloomy than usually considered.—*Proceedings of the Royal Society of Medicine.*

THE PATHOLOGY OF THE LIVING.

IN reviewing the history of surgery for the past half century one dwells with wonder and almost awe on its operative successes and on the daring of its votaries in entering new fields which were formerly in not only an unknown but a forbidden land. The fathers of men still living might have been among those who are said to have gathered at the house of the woman from whom Ephraim McDowell had removed an ovarian tumor, ready to take his life to atone for hers if she succumbed to his daring assault; now no embryo surgeon three weeks graduated from his hospital interneship would hesitate to open the abdomen merely to give temporary relief from suffering even when there was no question of saving life by the operation. Dazzled by the brilliancy of surgical therapeutics one often fails, however, to recognize the services that surgery has rendered to pathology and diagnostics. The internist, complaining that the surgeon has invaded his field, forgets that were it not for the surgeon this field might still be as barren as it was fifty years ago.

In the address in Surgery before the British Medical Association at Brighton last week, for an advance copy of which we are indebted to the editor of the *British Medical Journal*, Sir Berkeley Moynihan directed attention to this aspect of modern surgical achievement. In his address, entitled "The Gifts of Surgery to Medicine," the speaker showed how surgical research had solved many of the problems of internal medicine and cited a number of illustrations to demonstrate the gradually widening knowledge of morbid abdominal conditions based upon the study of what he called the "pathology of the living." In the pre-anesthetic and pre-antiseptic days "an acquaintance with the morbid processes attacking internal organs was based," he said, "upon two sources of information only—upon an inquiry into the details of the clinical history of any disease as it developed, waned, or progressed, and upon the examination of the parts involved after the death of the sufferer." Much no doubt was learned in this way, but the knowledge was based largely upon intuition and conjecture and it was subject to revision at any time; it lacked the certainty of that founded upon inspection of the living organs and tissues. The pathologist in those days was much like some biochemists of our time who think that once they are able to synthetize protoplasm they can create life, ignoring the fact that their analyses, upon which their syntheses must be based, are of dead protoplasm. That there is a wide gulf between the pathology of the living and that of the dead is as certain as that there is a cleavage in the chemistry of those two states. An instance of the latter is adduced by Sir Berkeley Moynihan in respect of the pancreas: "We know well," he says, "the great change that comes over all parts of the body after death; the face changes, wrinkles are smoothed away, the cheeks sink in, the eyes are lusterless, the orbits hollow. Other parts change equally, and among them the pancreas, perhaps, most of all. In a case of acute pancreatitis the gland at the moment of operation, seems one massive phlegmon—tumid, doughy, and with no abrupt margin. After death it appears to be merely a bruised and blood-stained organ. So with the gland in a state of chronic inflammation. To the hand of the operator it may feel large and densely hard, and it may be responsible for the obstruction and a considerable dilatation of the common bile duct. After death it seems hardly altered from the normal, and certainly in earlier, less exact days would not have attracted close attention."

We can notice only briefly a few of the changes in our knowledge of chronic abdominal disorders, effected by a study of the "pathology of the living," cited in this most interesting address. To refer to the pancreas again, the knowledge of the frequency of chronic pancreatitis and of its mimicry of carcinoma has come to us through observation made during operation upon the gall-bladder. The doctrine of gastric ulcer has been established by intraabdominal study; it is now known that the clinical picture of ulcer of the stomach, of a photographic accuracy such as would deceive the most acute diagnostician, may be due to infection or obstruction in the appendix or other part of the intestinal tract; it is known also that in 70 per cent. of the cases of cancer of the stomach the malignant process originates at the overhanging edge of a long-standing ulcer. An inspection by the surgeon of the abdominal organs during life has shown the internist that his former conception of dyspepsia as a functional or nervous disorder was erroneous and that in almost every case there is some real organic change in the stomach itself, or, more often, perhaps, in some other of the abdominal organs. Another lesson learned by pathological study *in vivo* is that the belief that gallstones usually or even frequently cause no symptoms is erroneous. The symptoms may not be such as the inexperienced would naturally refer to the gall-bladder, but they are almost invariably present, and "we now know that the earliest symptoms, the 'inaugural symptoms' of cholelithiasis are just as characteristic, just as certainly to be recognized, as those of the later sequels and avoidable complications. And more than this: the very little that was known of cholelithiasis in its clinical aspects has undergone a complete revision, with the result that we are often able to declare not only the presence of stones, but often the position of that which is causing the most serious trouble."

This study of pathology in the living, Moynihan says, has been made possible by three men—Morton, Lister, and Crile; the first introduced ether, the second taught us antisepsis, and the third abolished the pain of abdominal operations. To the latter Moynihan pays a warm tribute of praise. There was formerly, he said, one serious objection to abdominal operations in that they were always followed by more or less pain and shock. Now, the administration of a small dose of morphine and scopolamine before the operation, and the erection of a barrier around the field of operation by means of local anesthetics, so that for the time being no nerve impulses can be conveyed thence to the brain, make it possible to carry out with thoroughness any operative procedure within the abdomen without serious shock and without any intolerable postoperative pain. "We owe this entirely to Crile. The debt of surgery to this most acute, most versatile, and patient investigator was already a heavy one, but I think that to the surgeon of tender heart—and all surgeons surely are tender hearted—his latest work must bring the most profound satisfaction. . . . To the great discoveries of Morton and of Lister this of Crile seems to be the fitting completion."

POLIOMYELITIS AND ITS PERIODICITY.

Poliomyelitis is again knocking at the gate. There are indications that the unerring biennial periodicity of this disease will again become painfully manifest during the present summer. In 1907 New York with its 2,000 cases first felt the widespread ravages of a disease that heretofore had dealt its maiming blows chiefly in sporadic outbreaks. Since that year the arch-enemy of childhood has not been entirely banished from its lurking places. In 1909 and 1911 it again assumed epidemic virulence. This periodic recrudescence is not peculiar to any one locality, but is apparently a worldwide phenomenon. Thus epidemics occurred in Stockholm, Sweden, in 1887, 1895, and 1899; in Göteborg, Sweden, in 1903; in Sweden generally in 1905, when Wickman made his classical study of 1,025 cases; in New York in 1907, 1909, and 1911; in Steiermark, Austria, in 1909, and in Germany in 1909. Smaller epidemics have been reported from different places during the intervening years, but an examination of the above dates will show that although in the earlier years, beginning with 1887, there are gaps in the periodic repetition, nevertheless the disease returned with a rhythmic precision that cannot be regarded as accidental. There is a law governing the epidemiology of infantile paralysis, analogous to that controlling the periodic outbreaks of measles, scarlet fever, and meningitis.

The epidemic of poliomyelitis that prevailed in New York during the fall of 1911 strikingly illustrated one fact which has been observed in other epidemics and in other parts of the world, namely, that localities in a given city that are visited by the disease during one epidemic are practically spared when the disease returns two years later. A plausible explanation of this phenomenon is the hypothesis that the population in general in a given neighborhood during an epidemic acquire a relative and partial immunity, which protects the individuals and particularly the children during the next epidemic, which is compelled to expend its virulence on adjacent districts.

Poliomyelitis has been regarded as a disease of hot weather. But there is no direct correspondence between the height and persistence of the atmospheric temperature and the prevalence of the disease. For example, in the 1911 epidemic in Brooklyn the largest number of cases occurred during the month of September when the weather was fairly cool, and cases continued to be reported until early winter. In 1910, during an outbreak of poliomyelitis in Bristol, England, there was noted at the same time an unusual prevalence of typhoid fever. No such correspondence was to be observed in the last New York outbreak. Thus, whereas typhoid fever and diarrheal diseases reached their climax in August, poliomyelitis did not attain its maximum until September.

With the knowledge that poliomyelitis has followed a definite law of periodicity, one should be able to predict and to be prepared for future epidemics and more particularly for an impending one. There are signs, as stated above, that one is on its way. The Public Health Service reports for June the presence of 3 cases in New Jersey, 2 in Iowa, 2 in Michigan, 2 in Minnesota, 11 in Virginia, 5 in Ohio, 1 in Massachusetts, 2 in Wisconsin, and 1 in Louisiana. In the week ending July 12 1 case was reported in California. It is to be hoped that public health authorities will be alert to see that all cases of this disease are reported. Physicians in general should bear in mind the possibility of poliomyelitis in the presence of an obscure febrile illness in a child, even before the onset of paralysis, particularly if hyperesthesia and profuse sweating form part of the clinical picture.

ORGANOTHERAPY.

The physician is a hopeful creature, full of confidence in the future of the healing art, but just by reason of this somewhat prone to let his imagination outrun his judgment. He is apt to be sceptical as to the value of a new mode of treatment, but once this method has been shown to be really efficacious in the case of one disease he gives rein to his faculty of generalization and often overestimates the worth of the remedy and its scope of therapeutic activity. Thus, when the curative and prophylactic virtue of diphtheria antitoxin was demonstrated it was believed that the final victory over infectious diseases of whatever nature was in sight. Two decades have passed and infectious diseases are still with us. So again, when nearly a quarter of a century ago, George R. Murray cured a woman suffering from myxedema by means of an extract of the thyroid gland of a sheep, the belief spread that defects in any gland or organ might be compensated by feeding with the corresponding toxin from a sheep, an ox, or a pig. The animal extracts had a wide vogue for a time, but the hope of the medical profession in their universal applicability has not been realized.

Dr. Murray, to whom with Sir Victor Horsley, we owe the beginning of thyroid therapy, delivered the Address in Medicine at the meeting of the British Medical Association in Brighton, taking as his subject "Some Aspects of Internal Secretion in Disease." In this address, for an advance copy of which we are indebted to the *British Medical Journal*, Dr. Murray reviewed the progress made in our knowledge of the ductless glands and in the therapeutic application of their secretions and of those of other glands which have dual functions. It is not very encouraging to be reminded of the extremely limited application of this therapeutic method. The only really brilliant successes have been obtained in the thyroid treatment of myxedema and cretinism, for the results of the administration of parathyroid and pituitary extracts are very uncertain, and wonderful indeed as is the action of adrenal extract and invaluable as it is in medicine, its therapeutic value in Addison's disease is practically nil.

Returning to the use of thyroid extract in myxedema, it is of interest to learn that Dr. Murray's first patient with myxedema treated by thyroid extract is still alive and well, complete absence of myxedematous symptoms being maintained by a dose of 10 minims of liquid thyroid extract six days in the week, or 6½ ounces in the course of the year. Less than an imperial gallon of thyroid extract has therefore kept her in health for twenty-two years.

Notwithstanding the only partial success of organotherapy, as reviewed in this address, Dr. Murray is bravely hopeful of the future. "What we most desire," he says, "is to find satisfactory means by which we can supplement deficient secretion on the one hand and control harmful overactivity on the other. We have seen how far these objects have been attained in some cases. It is dangerous to attempt to forecast future possibilities, but it is not unreasonable to hope that in the light of further knowledge it may be possible to adequately supplement suprarenal insufficiency and so relieve the symptoms of Addison's disease. The treatment of Graves' disease and acromegaly will become more satisfactory as we acquire more adequate methods of checking the abnormal flow of secretion, when it is to be hoped that surgical measures will become unnecessary. Pancreatic diabetes may also prove to be more amenable to treatment by methods at present beyond our reach. Clinical medicine has already gained enormously from results obtained by experimental pathology, and we may look to the future with confidence for still further advances which will place more simple and efficient methods of treatment within our reach."

SANITARY RETROGRESSION.

After years of patient labors, finally culminating in an almost universal realization of the sanitary disadvantages of an atmosphere adulterated by smoke or other noxious matters, the decision of a lower court in New York declaring the smoke ordinanace of the Board of Health unconstitutional because too sweeping in its terms, and an unreasonable exercise of the police power of the State, because such conditions become necessary for the proper enjoyment of property in civilized communities, is, indeed, very discouraging. On the other hand nothing but such a radical decision can fully arouse the public, which has now been educated to a taste for better sanitary conditions, to their danger if this decision goes unchallenged. From this standpoint the decision is fortunate, since it affords the health authorities an opportunity to investigate more thoroughly the ill effects of a smoke-ladened atmosphere on the health of the community, and the best methods of remedying this evil, and then to formulate definite laws on the subject, covering every detail. At least on technical grounds, then, for lack of specificity, these ordinances cannot be attacked. Up to the present time no very definite laws could be framed because the question did not come up as strongly as other matters, though it was obvious to every one, layman or sanitarian, that so unnatural a condition as an adulterated atmosphere could not be anything else than harmful, depending in degree only upon the magnitude of the adulteration. Why make laws against food adulteration, in the consumption of which there is at least some choice, when air adulteration is allowed to go unmolested?

More recently, however, a great deal of material has come out on this subject, placing the knowledge on a more definite and scientific basis. It has been found that not only is plant life inhibited thereby, but that infant mortality as well as the general mortality has been heightened in the industrial centers where smoke-filled air is the rule rather than the exception. The mere fact that property cannot be enjoyed without defiling the air is hardly a sufficient defense, since civilization now understands that the enjoyment of life is the one all-important aim.

Surgeon J. B. Stoner of the U. S. Public Health Service, writing in the April, 1913, issue of *The Military Surgeon*, gives an interesting review of the subject of smoke nuisances. He points out the ill effects of a smoke-filled atmosphere upon the mental as well as the physical health of the community. Catarrhal affections, with their train of sequelæ, especially tuberculosis, are increased. The general efficiency of a community is appreciably lowered under these conditions, and the expense to the community in the increase of death and disease far overbalances any gain to the industries from the methods causing this condition.

These are tangible effects and well worth considering before putting the use of private property above the health of the community. Besides, the use of smoke-consuming devices would greatly lessen the nuisance; and since dense smoke is also a sign of imperfect combustion, more scientific stoking should be used. The greater cost of hard coal as a fuel, while an item in the industries, cannot be considered to the detriment of the health of the community, when the tendency now is to put even the convenience of the public ahead of all monetary or industrial advantages. The use of oil as a fuel,

which is now rapidly replacing other materials, will of itself solve this question, but until then the industries which must smoke should take themselves outside of the large cities.

Open-Air Schools for Healthy Children.

An interesting experiment was made last year in one of the public schools of Philadelphia in order to determine what advantage, if any, there was to the normal, not tuberculous or near-tuberculous, child in an open-air school life. Two rooms were selected having each about the same number of children of the same grade and age, of the same social standing, and living under similar home conditions. In one room the windows were kept widely opened, top and bottom, and the artificial heat was shut off except when the temperature fell below 50° F. The other room was ventilated and heated in the usual way and the windows were kept closed on most days. In the room with open windows the children wore extra wraps and had frequent drills and exercises. Dr. Walter W. Roach, the medical inspector, by whom the experiment was made (*American Journal of Public Health*, Vol. III, No. 2), found at the end of the school year that the pupils in the closed-window room had gained an average of one pound in weight, while those in the open-window room had gained two pounds. The latter kept wholly free from colds, were quicker to learn, more alert, needed less review work, were better behaved, and were more regular in attendance. The superiority of the children in this room was so noticeable, not only to the medical inspector but to the visiting school board, that the latter authorized the establishment of open-window classes in several other Philadelphia schools. It will be interesting to know the result of this second year's trial of the fresh-air school for healthy children.

News of the Week.

Reorganization at Tulane.—As a result of recent adjustments at Tulane University, New Orleans, announcement was made on July 14 that the medical department had been reorganized and would be known henceforth as the Tulane College of Medicine, consisting of four schools, each with a separate dean and staff. The four schools are the School of Medicine and Pharmacy, Dr. Isadore Dyer, Dean; the Post-Graduate School, Dr. Charles Chassaignac, Dean; the School of Hygiene and Tropical Medicine, Dr. Creighton Wellman, Dean; and the School of Dentistry, Dr. Andrew G. Friedrichs, Dean.

Examination Announcement.—An examination of applicants for appointment as Assistant Director of Educational Hygiene in the schools of the City of New York will be conducted by the Board of Examiners on Monday, September 29, 1913, at 9 A.M., at the Hall of the Board of Education, Park Avenue and 59th Street, Manhattan. Applicants must be of good moral character, graduates of medical schools recognized by the Regents of the University of the State of New York, and with one year of specialized experience in pediatrics. The present salary schedule for the position is as follows: First year, $2,500, with an annual increase of $100 until the maximum of $3,000 is reached, which shall be the salary for the sixth and succeeding years. Further details may be obtained upon application to Dr. William H. Maxwell, City Superintendent of Schools, Department of Education, New York.

Death Rate in New York.—For the week ending July 19, 1913, the death rate in New York City was 12.14 per thousand, representing a total of 1,250 deaths, as compared with a rate of 13.20 and a total of 1,309 for the corresponding week of last year. There was a considerable decrease in the infant mortality, the number of deaths of infants under one year of age totaling only 259, as compared with 328 for last year.

Mme. Curie's Plans.—The report that Mme. Curie intended to abandon her work in Paris and undertake the direction of an institute for work along her present lines in Warsaw has been denied. Mme. Curie states that the organization of the laboratory at Warsaw, her native town, will occupy her only during her vacation period, and that in the fall she will resume work at the Sorbonne.

The Parasite of Oroya Fever.—It is announced in the *Boston Medical and Surgical Journal* that Dr. R. P. Strong and his associates from the Harvard department of tropical medicine, now at work in Peru, have discovered the parasite of Oroya fever in the presence of minute intracorpuscular bodies in the red blood cells. These bodies have been previously observed, but their nature had not been proved. It is probable that they belong to the genus *Theileria*. The importance of this discovery is enhanced by the announcement that Oroya fever is a distinct disease from verruga peruviana, and not merely a severe initial fever of the latter, as has been generally held. Of general interest to parasitologists is the discovery that *Theileria* has been found pathogenic for man.

Marriage Reform Laws.—The State Legislature of Wisconsin has taken a radical stand on the question of the regulation of marriage and of the safeguarding of the race, and recently passed a bill making the granting of a health certificate a necessary requirement to the issue of a marriage license. Another bill passed in the closing hours of the session provides for the sterilization of criminal, insane, feeble-minded, and epileptic persons confined in State institutions.

Governor Tener of Pennsylvania on July 24 signed a bill passed by the Legislature, which provides that marriage licenses shall in future be issued only to those able to show that they are exempt from transmissible disease. Also such licenses will not be issued to imbeciles, epileptics, those of unsound mind or to a man who within a period of five years has been an inmate of a home for indigent persons unless he can show that he is physically able to provide support for a family. Furthermore, a marriage license may not be issued if at the time of application either of the contracting parties is under the influence of liquor or any drug.

Bequests to Charities.—The Hospital of the Protestant Episcopal Church of Philadelphia receives a bequest of $5,000 under the will of the late Rev. Dr. L. T. Chamberlain, to be used for the endowment of a bed in memory of his wife.

By the will of the late Rev. Leander Trowbridge Chamberlin, of New York, the sum of $5,000 is bequeathed to the Hospital of the Protestant Episcopal Church of Philadelphia for the endowment of a free bed.

By the will of the late Catharine H. Craig of Philadelphia the sum of $2,000 is bequeathed to the Children's Ward of the Presbyterian Hospital of that city.

A bequest of $6,748 will be paid to the New York Orthopedic Hospital under the will of the late Mr. O. E. Schmidt of New York.

By the will of the late Francis Way Smith of Philadelphia the sum of $47,000 is bequeathed to the Seaside Home for Children at Atlantic City, and the sum of $6,000 to the Chelsea Home for Children at Philadelphia.

The Thomas Morgan Rotch, Jr., Memorial Hospital for Infants, Boston, receives a bequest of $10,000 under the will of the late Mr. Charles D. Sias of that city.

Prof. A. von Wassermann of Berlin has been appointed director of the Kaiser Wilhelm-Gesellschaft für experimentelle Therapie at Dahlem, which was founded recently by the Kaiser Wilhelm-Gesellschaft zur Förderung der Wissenschaften.

Ophthalmic Institute.—The New York Ophthalmic and Aural Institute, now at 44 and 46 East 12th Street, which was founded by Dr. Herman Knapp in 1869, will move to its new building at Tenth Avenue and 57th Street on October 1, 1913. The new hospital building is a seven-story structure, especially planned for the treatment of diseases of the eye.

Washington State Medical Association.—At the annual meeting held on July 14 to 16 in Everett, the following officers were elected: *President-elect,* Dr. C. W. Sharples, Seattle; *President,* Dr. Cornelius J. Lynch, North Yakima; *Vice-Presidents,* Dr. J. R. Brown, Tacoma, and Dr. John Palmer, Seattle; *Secretary-Treasurer,* Dr. C. H. Thompson, Seattle. The next convention will be held in North Yakima.

Obituary Notes.—Dr. Samuel Blume of Riverhead, N. Y., a graduate of the Bellevue Hospital Medical College, New York, in 1867, and a member of the New York State and Suffolk County Medical Societies, died at Baker, Ore., on July 18, aged 68 years.

Dr. William Floyd Randall of Dushort, Pa., lost his life on July 16 as a result of injuries received in an effort to save a laborer who had fallen into a well and been overcome by gas. Dr. Randall was a graduate of the Baltimore University School of Medicine in the class of 1890 and of Jefferson Medical College in the class of 1892. He was a member of the Sullivan County Medical Society, of the Medical Society of the State of Pennsylvania, and of the American Medical Association.

Dr. Jerrold D. Ball, of Toronto, Ont., a graduate of the Toronto School of Medicine in 1874, died at his home on July 5, aged 67 years.

Dr. Charles S. Penfield of Spokane, Wash., a graduate of the Hahnemann Medical College and Hospital of Chicago in 1880, and a member of the Washington State and Spokane County Medical Societies, died at his home suddenly on July 7, aged 56 years.

Dr. Thomas Wilson Monroe of Milford, Mass., died at his home, after a long illness, on July 10, aged 67 years.

Dr. George T. Kimball of Kenosha, Wis., a graduate of the University of Pennsylvania Medical Department, in 1881, and a member of the American Medical Association and the Wisconsin State and Kenosha County Medical Societies, died suddenly of paralysis, on July 10, aged 55 years.

Dr. Abraham P. Frick of Aransas Pass, Tex., a graduate of the University of Pennsylvania, Medical Department, in 1861, died at his home on July 11.

Dr. William Taussig of St. Louis, Mo., a graduate of the University of Prague in 1844 and of the St. Louis School of Medicine in 1850, died at his home, from pneumonia, on July 10, aged 87 years.

Dr. Harry Daniel Abbott of Danvers, Mass., a graduate of Tufts College Medical School, Boston, in 1904, and a member of the American Medical Association and the Massachusetts State and Essex County Medical Societies, died at his home on July 16, aged 33 years.

Dr. Charles Reed Pratt of Bridgeport, Conn., a graduate of the Yale University Medical Department, New Haven, in 1905, and a member of the Connecticut State and Fairfield County Medical Societies, died at his home after a short illness from malignant endocarditis, on July 15, aged 34 years.

Dr. Charles McAllister of Spencer, Iowa, a graduate of the Berkshire Medical College, Pittsfield, Mass., in 1865, and a member of the American Medical Association and the Iowa State and Clay County Medical Societies, died at his home in South Lee suddenly, on July 20, aged 73 years.

Correspondence.

RÖNTGENOSCOPIC EXAMINATION IN GASTRIC DISEASE.

To the Editor of the Medical Record:

Sir:—It is to be hoped that many more clinicians will follow, in a way, the example of Dr. John Dudley Dunham, in regularly submitting their patients with gastrointestinal symptoms to Röntgenologic examination (Medical Record, June 14, 1913). I am sure, however, that a wide experience with expertly made Röntgenologic examinations will finally lead to conclusions very different from some of those which Dr. Dunham has so far formed.

The experience of our German confrères, who have made such an extensive research in this department, as well as that of several skilled American Röntgenologists, has led them to place great reliance upon this method; my own experience, while greatly limited as compared to that of many others, is such that I am thoroughly convinced of the exceeding value and importance of Röntgenology here.

Dr. Dunham places so much emphasis upon the fluoroscopic method as the one to be employed, that his attitude as formulated in his conclusions cannot be regarded as entirely justifiable, at least in the opinion of those who are fully familiar with gastric Röntgenology. Fluoroscopy is of a certain value here, but my own opinion, and I believe this will be coincided in by the majority of Röntgenologists, is, that fluoroscopy is decidedly secondary in importance to the method of serial Röntgenography, especially after the technique of Holtzknecht and Haudek. For one thing, it is impossible to make an accurate tracing of a fluoroscopic image of the stomach; while one is making a line six inches in length upon one side of the stomach, the organ has completely changed its outline on the other side by reason of peristalsis.

A series of "moment Röntgenograms," however, presents an exact outline. From these one can

study at leisure the appearances presented, consider the whole field shown, and assimilate the relationships existing between things seen in different parts of the fields; this cannot be done during fluoroscopy; the eye which is fixed upon the peristalsis of the body of the stomach does not see what is going on in the duodenum, or at the ileo-coecal junction; if I had to choose between the two expedients, I would unhesitatingly cast out fluoroscopy in favor of serial Röntgenography. The very nature of the fluoroscopic examination; its fleeting duration; the fact that so many different movements are going on at once in different areas; the impossibility of taking in and correlating the appearances in different and distant parts of the field, all render this method incomplete as a diagnostic procedure, even in the hands of the experienced Röntgenologist; the clinician cannot give the time to educate himself in gastric Röntgenology if he is busy enough to have a use for it, and he will find himself unable to devote the required time to the art itself if he attempts to carry out the procedures thoroughly.

I would change Dr. Dunham's conclusion No. 9 to read: "The *worst* results in gastric diagnosis will be attained when the clinician himself employs the fluoroscopic examination as one of his own clinical methods."

G. H. Stover, M.D.

Denver, Col.

LUNAR CEREBRATIONS.

To the Editor of Medical Record:

Sir:—I was very glad to see an article by Dr. C. P. Oberndorf in the July 5 Medical Record inasmuch as it mentioned the full moon in relation to certain human phenomena.

Some time ago this seemed so ancient an expression that the editor of the Medical Record declined with thanks some lunar observations made by me in relation to menstruation and labor. The article was sent to several editors, but they would not permit pale Cynthia to enlighten their readers. She would have told them not to expect confinements at the time of the full moon, but for gynecological examinations, unless there is need of haste, to select the period of the full moon as giving surety that the patient would be free of menstruation. Not that the moon produces effects more than the clock produces time. In this connection an ancient writer wrote: "The moon is an excellent clock, if not the cause of many surprising occurrences, it gives a just indication of them." There are probably certain electrical conditions which are coincident with the phases of the moon. It is certain that when it is full all human creation is more or less stimulated. The woman appears more so than the man. She is the first to notice the full moon. It is probable that in cases of great illnesses the vital spark is more apt to be retained at that time, so that we can sometimes gain credit for prognosis within limitations at that time. The full moon is the time for courtship and marriage, and Easter, and the most ancient celebrations and saturnalia were set at that time. There was a sexual cause for this. The majority of women were and are free of menstruation at that time, so that they were free to enjoy themselves by the light of the moon. The period of the dark moon is one of more or less depression. It is most frequently at such a time that we read of suicides.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

HOSPITALS AMALGAMATING—ANOTHER HOSPITAL DISSENSION—ROYAL SANITARY INSTITUTE—INSURANCE ACT, FIRST REPORT AND CRITICISMS ON ITS WORKING—RED CROSS AND QUEEN ALEXANDRA.

London, July 11, 1913.

Two of the London hospitals which have schools attached are about to amalgamate, sell their sites, which have increased enormously in value, and erect a joint hospital in a neighborhood where they will probably be more useful. They are St. George's and the Westminster. St. George's occupies a site at Hyde Park Corner, now the center of a most fashionable district, though when first opened it was near a poor, overcrowded part whence many patients came, but that has been completely transformed. Yesterday a special court of the governors agreed to accept an offer made of £460,000. This with the amount expected to be realized by the Westminster's site will enable a joint hospital to be built on a site of eight acres offered and have a considerable amount of their investment funds untouched. Possession may be retained for two years while building their new hospital. From a financial point of view the transfer seems a beneficial one, as it certainly would be for the poor for whom the hospitals are maintained. Resolutions empowering the committee to carry out the sale and amalgamation were passed *nem. con.* It is said that a fine modern hotel will be built on the site.

I told you last week about the trouble at St. John's Hospital for Skin Diseases. This week a similar one has been made public concerning Mount Vernon Hospital for Consumption with its branch or sanatorium at Northwood. Again the lay managers have dismissed two of their physicians not only without consulting the medical board but in direct opposition to it. This seems the immediate grievance though others are alleged. The other members of the staff, consulting and active, have sent in a joint letter resigning their appointments as from the 20th of July next. Report says that the committee meant to replace the two physicians they dismissed by two others who are known. Of course the dismissal is illegal and after the judgment in the other case the committee must see that and ought not to waste public money in another appeal to the law courts. The committee refused to meet the Medical Board in a conference respecting the above named and other questions.

The Royal Sanitary Institute's annual congress was opened on Monday at Exeter where about 1,000 experts and persons interested in hygiene attended. The Mayor of Exeter gave an official reception and Earl Fortescue delivered his presidential address in the evening. He dealt with the question of rural housing and the responsibilities of county authorities for sanitary defects. He combated the notion that bad cottages were the cause of migration to the towns—a movement so marked 500 years ago that an act was passed to check it. The self-same exodus was observable in Europe, America, and the antipodes. It was the landowner's business to build cottages for his laborers and the majority did so. But it seemed nobody's business to house the other villagers who worked for the community at large. Cost was at the root of the problem. If the combined wisdom of scientists and hygiene experts could devise cheaper materials and methods of building cottages healthy as well as cheap they would add one more

to the many obligations already owed to them by the public.

On the second day Dr. Wynter Blyth gave an address on Immunity, after which Dr. E. Latham read a paper in which he pointed out how far we are from the results which were promised from the Insurance Act and the establishment of the Sanatorium system. He thought it very doubtful whether any progress had taken place during the past year with regard to tuberculosis. The sanatorium benefit in London was in a state of hopeless muddle. He gave instances from his patients in St. George's Hospital—one he had to keep in St. George's from December to June waiting for steps to be taken in spite of repeated applications to the Insurance Committee; another was kept four months before receiving the benefit provided by the Act. They were told that thousands were in the sanatoria—an answer which might satisfy politicians but not men who knew what sanatorium treatment was. The net result was that the so-called benefit was Poor Law medical relief under another name. One reason for so deplorable a state of things was the employment of administrative officers and advisers to the committees and in many cases committing the treatment to men with no special experience of the disease. Still he would not despair that some orderly scheme might be evolved.

Dr. Boobbyer, of Nottingham, said his experience was that patients in the sanatoria regarded themselves as State prisoners on a holiday and all work as an evil to be avoided. So far, too, patients had been kept for too short periods to be of use.

Dr. Sandilands, of Kensington, blamed misguided public opinion leading to wholesale admissions and exhaustion of funds. Dr. Macfie, tuberculosis officer of Essex County Council, said that the only way of dealing effectively with the disease was domiciliary visitation and examination of every certified case.

The first report of the National Insurance Act, Part I (Health Department), has appeared in the form of a bulky blue-book of 700 pages. It is crowded with statistics relating to the approved societies, trade unions, deposit contributors and other persons. Up to the end of May last the amount paid to societies was £3,934,042. Of this more than £3,600,000 was paid to them in advance. An account of the normal work of an Insurance Committee is given from which it seems that the administration of sanatorium benefit is growing rapidly. Claims coming in each day are registered and a visit from the tuberculosis officer arranged after which applicants are informed whether they are recommended for treatment, doctors are notified of those who are to have domiciliary benefit and traveling managements made for those who are to go to sanatoria. Details are also given respecting the entrance of doctors on the panel and the keeping and correcting the list of these gentlemen.

During the first four months after July 15 last year, 2,865 applicants received sanatorium benefit. By April 30 this year the number had increased to 7,464 of those who were or had been in institutions, while 2,167 were treated through dispensaries, and 4,993 at home. The cost chargeable to the sanatorium benefit fund (excluding administration of the benefit) on April 30 was £122,123. At present in England alone over 200 residential institutions have been approved for the reception of insured persons and their dependents, providing for about 8,000 cases, and 189 dispensaries have also been approved.

The agreements with doctors for the panel were at first for three months, at the expiration of which nearly all were voluntarily continued. It is estimated that between 80 and 90 per cent. of the doctors in industrial practice are available for the insured population.

A conference of approved societies was held last week when the president said though the Act was imperfect it was too early to commend it. But some of the proposed changes were excellent; *e.g.* a six-month's card instead of the present was not only desirable but necessary. But to make the Act compulsory "would both mend and end it."

The issue of this report has excited criticism of many of the managements and restatement of various complaints, some of them involving the panel doctors. The Stepney medical health officer says that 90 per cent. of those certified for sanatorium did not apply for the benefit. Inquiring into this he found that they were required to go to the West of London to be examined and thereby lost a day's pay, no arrangement being made to admit in the evening. Further they were required to produce their insurance cards which were kept by the employer. To ask for it excited suspicion, and if the reason were stated many employees objected to employ consumptives. Some cases, too, were not fit to leave their homes, much less travel across London. The sub-committee, which considers complaints against panel doctors, has dealt with several unimportant cases and reported them groundless. In a case of one practitioner about whom a number of charges of neglect were made he was advised to arrange to transfer his list to a neighboring panel doctor. In another a severe reprimand was passed notifying that any other charge if substantiated would be reported to the commissioners with a recommendation to remove him from the panel.

A Committee of the General Medical Council has had under consideration some of the complaints that have been brought under the notice of the Insurance Commission by Sir D. MacAlister (President of the Council). The most important is the charge that practitioners have been required to furnish certificates not only of incapacitating illness but of its exact nature. That the council say would involve a breach of confidence. So obvious is this that Sir R. Morant, replying for the Commission, says no instance of such a demand has come to his knowledge. The misconception arises from the fact that some societies make such a condition with their members and certificates of the kind are of course at the discretion of the members holding them so that breach of confidence cannot occur. He adds that probably the societies would assent to a uniform wording showing the certificate to be confidential. It is thus seen desirable that the doctors should combine to press on the societies a reasonable solution.

On Monday a meeting in London decided to form an association of nonpanel doctors, who will accept no service under the act unless the following amendments are made: Free choice of doctor, an income limit, no section to be in a permanent majority on any insurance committee. There are local nonpanel societies in several districts, and it is hoped the London medical committee will act as a co-ordinating central body.

The Hearts of Oak Benefit Society's council has

protested against Mr. Lloyd George's "misleading statement" that his amending bill had been drafted after consultation with the Friendly Societies. They had had no invitation, direct or indirect, and anyone attending such consultation, "if it were held, had no authority to speak for Friendly Societies in general."

The movement for opening "tuberculosis dispensaries" in many districts is making some progress. A meeting was called at Lady Robert Cecil's house in support of one in St. Marylebone, of which the Mayor expressed approval and Dr. Squire pointed out that poverty—one cause—prevailed in some part of the district. Dr. Halliday Sutherland said the Edinburgh system was a result of voluntary effort, whereas the state "had created a howling wilderness" of legislative enactments. In Chelsea the advocates of the system seem to have formed a league for its promotion and they secured the presence of Princess Marie-Louise of Schleswig Holstein at a drawing-room meeting in its support. At this Drs. Cunnie McCall, McKeith, and Camac Wilkinson spoke. The last-named said he was chairman and director of the league and declared himself responsible for the introduction to London of a special form of treatment. It is said this is a modification of the method of using tuberculin. It is to be hoped we are not to be troubled with claims for recognition of every deviation of usage or repetition as a specialty.

There was a baby show in East London last week, where Dr. Carter, who judged the infants, reported a deterioration from last year's show. Of fifty-five babies forty-four were naturally fed by their mothers; twelve per cent. below last year's figure. He had noticed in another part of London the same depreciation, where 1,000 had been shown, and he attributed it to the "national calamity under which they lived—he meant the Insurance Act." When the fathers could not get their cards stamped the mothers had to go to work and leave the children unattended.

Queen Alexandra on Tuesday presented the British Red Cross badge to the medical men, nurses, and orderlies who had voluntarily gone to the Balkans during the recent war there and established hospitals for the wounded in the several countries.

7. An Unusual Case of Fracture of the Patella (Treated by Immobilization). D. P. Penhallow.

2. **Addison's Disease.**—G. M. Piersol reports four cases of this condition. He states that the most frequent pathological change noted in the suprarenal capsules in this condition is tuberculosis. Other lesions observed in these organs are simple and inflammatory atrophy, carcinoma, sarcoma, melanotic tumors, hypernephroma, and even gumma and echinococcus disease. Necrosis such as was observed in one of the author's cases is not mentioned as a usual adrenal lesion. It is interesting in connection with the chromaffin theory to recall that the lesions in this case involved chiefly the medulla. It is pointed out that there exists a form of Addison's disease apparently dependent upon a primary atrophy of both the adrenals, in which there is an absence of pathological processes in other organs. In this condition the true adrenal tissue has almost entirely disappeared and the glands are converted into thin parchment-like structures. This form of the disease has been investigated by several observers and is emphasized by Strümpell, who regards it as the only true primary type of Addison's disease. It is possible, therefore, that it is incorrect to consider such cases as have been described by the author as Addison's disease, and that one should look upon them merely as examples of a secondary symptom-complex resulting from accidental adrenal involvement.

3. **Experimental Production of Gastric and Duodenal Ulcers.**—E. C. Steinharter points out that many facts suggest the theory that the colon bacillus is in some way causally related to the production of gastric ulcer in man. Up to the present time, however, although numerous experiments have been made by many investigators, no etiological connection could be established. It has long been known that an emulsion of colon bacilli in the presence of free hydrogen ions is agglutinated in from one to four hours when incubated at the body temperature. Gastric juice of high acidity possesses this agglutinating power. It occurred to the author to investigate the results of injecting intravenously emulsions of clumped colon bacilli. Active strains of colon bacilli in broth emulsion were accordingly agglutinated with weak solutions of acetic acid and hydrochloric acid. In some of the experiments a weak alkali was added. When 2 c.c. to 3 c.c. of such an emulsion were injected into the ear vein of rabbits, such an injection was uniformly followed by the formation of a gastric or duodenal ulcer within 24 hours.

4. **Operative Treatment of Spastic Paralysis.**—H. E. Harris, generalizing from his observations, concludes that excellent results have followed subcutaneous tenotomies, whether they were zigzag or otherwise, and this has an important bearing on the question as to whether there is danger of permanent and undesirable lengthening of the tendo-achillis after free division; such conditions were especially looked for in the 22 cases discussed and none were noted. It would seem, therefore, that the open operation is not at all necessary. It also seems that alcoholic injections have not in the cases reported prevented the return of spastic contractures. Children who have not taken a step, have been able to walk as a result of simple division or resection of the adductors and hamstrings, and apparently much can be expected from the Tubby procedure of transferring the pronator radii teres to work as a supinator. Although the operative procedure may be that properly suited to the individual case, it has also been shown that without careful after-treatment and the long-continued after-use of plaster and apparatus the various operations are likely to be of little use.

5. **Endocarditis in Children.**—L. W. Gilbert believes that acute endocarditis should be considered as acute over a much longer period than has been the custom. Treatment should be carried out for months and perhaps years, until all possible signs of acute disease have disappeared, and even then, until adolescence is passed, at least a certain amount of restraint should be exercised.

6. **Fracture of the Carpal Scaphoid.**—W. P. Coues notes that fracture of the carpal scaphoid in childhood or young adolescents is one of the rarest of injuries. The developmental conditions of bone about the wrist at these ages are probably largely responsible for this. When children receive injuries to the wrist the possibility of this fracture must be thought of. Particularly is this true in cases where there is no tenderness over the lower end of the radius and ulna but pain and tenderness over the dor-

sum of the hand just distal to the lower end of the radius and in the snuff box. A marked swelling of the dorsum of the hand, stopping abruptly at the radius and ulna, which was present in the author's case, may be of considerable diagnostic importance. A radiograph should always be taken of these injuries and the scaphoid scanned searchingly for possible fracture.

2. The Internal Secretions as They Concern the Gynecologist.—S. W. Bandler states that the age at which genital maturity takes place has an important influence on skeletal growth, and early maturity is associated with short legs, for the ovaries elaborate a hormone which stimulates the process of ossification. The effect of late maturity of the ovaries is to increase the height, especially the length of the legs. The element of the ovary which is responsible, directly or through modification of the hypophysis or other gland activity, for the constitutional physical changes which characterize puberty is not known, but some assert that it is possibly the interstitial gland structure. The author next discusses the question of relative and actual amenorrhea, especially when this condition is associated with obesity and occurring, as it often does, many years before the awaited climacterium approaches. It is recognized by all that the ovaries preside over menstruation and exert a trophic influence on the uterus, senile atrophy and lactation atrophy being simply physiological processes due to the cessation of ovarian activity. There is a certain type of case in which menstruation gradually diminishes, the menstrual molimina become less pronounced and the uterus and ovaries smaller; associated with which there is a progressive gain in weight. Little can be done to reduce such patients in weight or to restore their menstrual function. The author characterizes these cases by the term "precocious menopause," and has previously explained them on the basis of an equal and harmonious diminution of function of the thyroid and ovaries. A lowered function of the posterior lobe of the hypophysis, with a coincident disturbance in metabolism, is responsible for the gain in weight and for the ovarian atrophy, and in all probability is in many cases associated with lowered thyroid function. The ovaries bear some relation to certain excessive uterine bleedings. They are, after all, the cause of menstruation, and the vast majority of cases of relative or absolute amenorrhea are due to involvement of the ovaries, directly or through the influence of other glands or certain diseases. Why may one not expect symptoms of the opposite extreme with overfunction on the part of the ovaries, if they produce a congestion or hyperemia of so marked a nature that only slight disturbances in the uterus are necessary to result in menorrhagia or metrorrhagia? In diseases involving the thyroid or hypophysis, inaction on the part of the cilia is regarded as a possible cause of sterility, and the ovary and thyroid or some of the other internal secretions are regarded as possibly responsible. The intimate relation between the ovary and thyroid is such that it is more than probable that changes occurring in the ovaries themselves influence the thyroid to underfunction or to overfunction. These anomalies in thyroid secretion, whether in the way of amount or quality, concern the gynecologist because of the alterations which they produce in the digestive system, in the nervous system, and in the psyche. One is concerned in the climacterium with a progressive failure on the part of the ovaries to produce their normal secretion. Coincidentally, and because of this failure, there occur alterations in other glands in the body, the thyroid being the one most particularly involved.

4. The Sense of Smell in Diagnosis.—R. E. Coughlin points out that the odor about a typhoid fever patient is quite marked, owing to the emanations from the body and the discharges, especially if there be diarrhea. In smallpox there is said to be a peculiar odor, especially during the stage of suppuration, like the odor of sweet potatoes, according to some. In scarlet fever the breath often has a heavy, sweet odor. In diphtheria there is a very characteristic odor about the patient, depending upon the severity of the infection and the extent of the membrane. The odor is fetid, as a rule, when the membrane reaches the back of the nose. In septicemia and pyemia the odor of the breath is foul. In pulmonary tuberculosis there is a characteristic odor about the patient, aside from the odor of the breath. This odor is pungent and emanates from the skin of the patient. It may be perceived on the underclothing after removal from the body. In rheumatic fever there is an acid sour smelling odor from the sweat glands, which is not noticed in any other disease. In diabetes mellitus there may occur the sweet odor of the breath sometimes called "the acetone breath." In ulcerative stomatitis there is a fetid or putrid sore mouth condition, with a very bad odor to the breath, and this is also the case in mercurial stomatitis or ptyalism. In suppurative tonsillitis the odor of the breath is foul, and the odor of the discharge is very characteristic. Dyspepsia in itself may produce a bad odor to the breath, as will any of the toxic conditions affecting the alimentary canal. In cancer of the stomach the vomited matter consists of food and mucus in grayish or dark sour smelling fluid. Children with gastrointestinal conditions have a sour smelling odor about their mouths and bodies. In some appendicitis cases there is the characteristic odor of the discharge, denoting ulcerative gangrenous appendicitis. In severe toxic conditions affecting the peritoneum the odor of the breath is foul, and this condition also obtains in intestinal obstruction. Bronchiectasis is also accompanied by a foul breath; likewise abscess of the lung and empyema. Gangrene of the lung has the distinction of producing the worst odor of all.

6. Tuberculosis in the United States Army.—I. W. Brewer presents statistics which show that for the ten years ending with 1894 the average admission rate in the United States Army for tuberculosis of the lungs was 3.24 in a thousand. There was a decline in the rate until it reached 1.59 in 1896. With the advent of the war with Spain the rate ran up to 3.70, increasing to 4.92 in 1900. By 1903 it had fallen to 3.89, but up to and including 1907 it remained above four in a thousand. In 1908 it fell to 3.81, but there was a slight rise in 1909, followed by a marked fall in 1910, when the rate of 3.12, the lowest since 1896, was reached. During 1911 there was a slight rise.

9. Work of Women in Department Stores.—Josephine Goldmark points out that the New York law provides that women may not be employed in factories more than ten hours in one day and fifty-four hours in one week; but that for adult women in department stores there is no legal limitation of work whatsoever. New York is almost the only great industrial State which thus discriminates against the girls and women in department stores. In twenty States the law governing factories governs employment in department stores also. Three States (California, Colorado and Washington) prohibit more than eight hours' work in one day; other States like

Illinois, Louisiana, Kentucky, Maryland, Michigan, Wisconsin, and even New Jersey, prohibit more than ten hours in one day. New York provides a limit only for girls under twenty-one years; and, since no proof of age is required, this law is practically impossible of enforcement. It is true that girls in department stores are not subjected to the speed, monotony, and complexity of machinery, but the girl behind the counter suffers greatly from the constant standing, continuing at any rush season literally throughout the day. Many girls complain of broken arches and varicose veins. There is also a great nervous strain in being always on one's good behavior, and of an even temper, suiting the tastes and whims of customers. The girl needs the protection of the law as urgently as the factory worker. Injuries to the pelvic organs result from long hours of standing.

3. Skin Diseases Among the Indians.—E. S. Lain points out that the full-blood Indian is not subject to the variety of dermatological lesions found in the white race. Full-blood Indians are almost free from such skin diseases as may be produced or excited by menstrual disorders or an overtaxed nervous system. Though their food is limited in variety and poor in quality, they do not have many of the skin lesions which are ordinarily attributed to such causes. Previous to civilization, baldness was probably unknown among the American Indians. While syphilis is common among the different tribes, it is not as prevalent as is generally believed. Tuberculosis of the lymphnodes, particularly of the cervical region, is very prevalent and might be largely prevented if more prophylactic measures were enforced by the United States Indian Service. The uncivilized Indian apparently is yet free from pellagra and almost immune to cancer. Might we not find in a study of his simple outdoor life, limited foods, the character of his skin, etc., a clue which may lend material aid in the discovery of the etiology and propagation of these diseases among the white races?

4. Collateral Circulation in Gangrene of the Foot.—By J. E. Thompson. (See MEDICAL RECORD, July 5, 1913, page 37.)

6. The Cutaneous Affections of Childhood.—A. Schalek lays down two general rules that should govern the treatment of these conditions. The first is the correction of any causative or aggravating complication. There are only a very few drugs which have any direct action on the skin. Those used for adults, such as arsenic, mercury, iodides, etc., must be used with great caution, partly on account of their general effects, partly because the child's skin is much more liable to drug dermatitis, which might complicate or disguise the original trouble. The drugs usually needed are simple and are indicated by the internal complications. An occasional purge with calomel or some other laxative, an iron tonic, and possibly a diuretic are usually all that is necessary. Antipyretics and opiates should be avoided as much as possible. The second general rule applies to the local management. It should be rather conservative than aggressive. The natural tendency of the skin is to recover to a normal condition if given a chance. Protection of the diseased skin is of the utmost importance. This means avoidance of irritations of whatever nature, exposure to air, water, heat or cold, scratching, the action of physiological and pathological secretions, and old and dried-up applications, etc. The number of the local applications which are necessary is limited. The tender skin of children does not tolerate and does not need any strong and stimulating action. The efficiency of the treatment does not depend so much on the knowledge of a great many different remedies as on the skill to recognize the indications and the proper method of application.

8. Hygiene of the Lead Industries.—A. J. Carlson and A. Woelfel offer two practical suggestions: (1) The lead carbonate is so much more toxic than the lead sulphate that lead workers as well as the state should aim at the elimination of the use of the carbonate in all industries in which this is possible. (2). In addition to taking other prophylactic measures, the lead workers should drink a glass of milk between meals (say, 10 a. m. and 4 p. m.), in order to diminish the chances for any swallowed lead to be dissolved by the free hydrochloric acid of the gastric juice, as in some persons there is a considerable secretion of gastric juice in the empty stomach.

13. The Treatment of Anginal Pains.—C. L. Greene concludes that while recognizing its wide variability, one should assume the unity of pain of cardiac origin and base the therapy on the chief causative factor—the cardiac exhaustion. The wide distribution of cardiac pain in the superficial sensory areas has led to misinterpretation of the lesser degrees of pain of the same origin and, hence, to excessive neglect and diagnostic error. The efficient treatment of cardiac pain in the broader sense resolves itself into the management of an insufficient, overfatigued heart muscle. Mental and physical rest and regulated exercise offer the best means of restoring a proper circulatory balance. A proper valuation of the subjective symptoms of cardiac overstrain, early oversight, and the timely and judicious treatment of cardiac lesions is quite as important as is the early recognition and treatment of tuberculosis.

3. The Process of Digestion.—E. E. Goldmann finds that the process of digestion coincides with a cellular reaction which takes place in the connective tissue of the mucous membrane, a reaction having for its principal feature an immense concourse of two kinds of cells, phagocytes capable of being stained during life and acidophile

cells. The author has found a similar reaction in the animal body under the most varied conditions. If, for example, a rat is purposely infected with trichinosis, masses of pyrrol cells and acidophile cells are found in the tissues surrounding the trichinous deposit and even in the trichinous capsules. In the neighboring lymph glands all those changes take place which occur in the cecal glands during digestion. In a prepared specimen of carcinosis of the peritoneum of the mouse, it was seen that the carcinomatous nodules lying in the mesentery are dark blue, whereas the intestine has taken the stain lightly, and microscopical examination proves that there has been a great accumulation of pyrrol cells on and around the carcinomatous nodules, whereas the intestine is almost quite free from these cells. The carcinoma has therefore diverted the pyrrol cells from the intestine and drawn them to itself. This cellular reaction is very similar to and perhaps identical with the one which Schlecht, Schittenhelm, and their co-workers have recently brought about by the parenteral administration to an animal of albumin derived from a different source and by anaphylaxis both in the blood and also locally. All these various conditions have a basis in common—namely, that the organism resists the entrance not only of foreign bodies but also of blood or cells from foreign sources, and when they have entered it may endeavor to convert them respectively into a part of its own fabric or into its own blood and cells.

4. **The Blood and Cerebrospinal Fluid in Mumps.**—A. Feiling reports a case in which a clinical picture strongly suggestive of meningitis was presented, and the clinical diagnosis was supported by the examination of the cerebrospinal fluid. The two together constitute a fairly complete proof of the existence of an inflammatory lesion of the meninges of the brain and spinal cord which undoubtedly followed mumps and for which no other cause could be found. From this case and from the accounts of the other quoted cases the following conclusions seem justifiable: (1) that a lymphocytosis of the cerebrospinal fluid occurs in mumps, when that disease is complicated by meningitis or by lesions affecting the cranial nerves; and (2) that a lymphocytosis has been found in cases of mumps which have presented no clear clinical symptoms of any organic lesion of the nervous system. Finally, from a consideration of the changes found in the blood and cerebrospinal fluid, one is justified in assuming that the virus of mumps excites an inflammatory reaction in the body whose characteristic feature is a great aggregation of lymphocytes.

2. **Carcinoma of the Prostate.**—R. J. Willan presents a study of this subject based upon thirty-three cases. The average duration between the onset of symptoms and the patient seeing a surgeon was fourteen and a half months. The average age was 61. The onset symptom was increased nocturnal frequency of micturition in 40 per cent., and gradual obstruction to urination in 30 per cent. of the cases. Pain was variable and not characteristic. Urinary obstruction was a marked feature—72 per cent. had complete retention, and a further 24 per cent. partial retention. Hematuria was not common; probably 82 per cent. were without bleeding. On rectal examination 70 per cent. showed hard nodules, with fixity of the gland. The average duration of the disease from onset of symptoms to death was twenty-eight months. Young's statistics that 21 per cent. of removed prostates show a malignant tendency cannot be ignored. If these figures are accepted, it is a surgeon's duty to remove the gland by operation immediately it begins to cause symptoms. The risks of the operation then are smaller than the risks should malignancy supervene. The treatment recommended when a diagnosis of carcinoma has been made is as follows: In the absence of residual urine, give a urinary antiseptic, with opium for the pain when necessary. If there is residual urine, begin catheter life, using a large-sized hard catheter; give a urinary antiseptic, with opium if necessary. If there is obstruction, or, if catheter life is intolerable, establish a permanent suprapubic drainage.

3. **Surgical Milestones.**—R. C. Brown describes five important surgical milestones, marked by the years 1836, 1847, 1867, 1892, and 1895. The modern system of nursing had its commencement in 1836. The credit of inaugurating the new order of things belongs to Germany, for it was at Kaiserwerth that the institute for training deaconesses was founded, and it was at this institute that Florence Nightingale acquired the practical knowledge which enabled her afterwards to turn her remarkable gift of organization to such brilliant account. Chloroform was used for the first time in a surgical operation in the Edinburgh Royal infirmary on November 15, 1847. Sir James Simpson made the first experiment with chloroform in his own house on November 4, 1847. In 1867 the antiseptic or aseptic method of treatment was introduced by Lord Lister. In 1882 very valuable information was communicated by Koch in reference to the tubercle bacillus, although its existence had been discovered by Baumgarten a few years previously. The *x*-rays, one of the most important auxiliaries to the surgeon of the present day, were discovered in 1895.

Serodiagnosis of Pregnancy.—Veit, the old master of obstetrics, having given a brief outline of Abderhalden's methods, expresses himself very favorably on these and analogous resources for the future. The clinic alone must decide their value. We have already had methods for the diagnosis of early pregnancy and Abderhalden's method is simply such another with a good theoretical justification. The entire subject of early pregnancy, whether normal or pathological, must be restudied from this viewpoint. Aschner, one of Veit's assistants, who has recently made elaborate investigations into the serodiagnosis of pregnancy, comes to the following conclusions: The serum of healthy gravidæ reacts positively to the Abderhalden test at all stages. Extrauterine and pathological pregnancies also react positively whenever a living ovum or living placental tissue is present. Serum from healthy nongravidæ invariably reacts negatively. In gynecological affections he found here and there a weakly positive reaction in disturbances of the ovarian function and cancer of the uterus. As yet he cannot say whether these are due to technical errors or to something which militates against the possibility of a universal law. The methods should be investigated with reference to ovarian disturbances (chlorosis) and with disintegration of protein with especial reference to eclampsia. The author would always check the optic with the dialysis procedure.

Dietetics of Cardiac and Vascular Disease.—Vaquez and Cottet conclude their serial article as follows: In the normal condition the daily excretion of water and chlorides must greatly exceed the nocturnal excretion. There is a diurnal polyuria and polychloruria. In subjects with disturbances of the renal functions corresponding to the old clinical type of interstitial nephritis, the nocturnal excre-

tion of chlorides greatly exceeds the diurnal secretion of water and chlorides during the day. There is therefore a nocturnal polyuria, and polychloruria. In persons who have disturbances of circulatory hydraulics, especially cardiac insufficiency, supposing that contracted kidneys do not coexist, the relations of water and chlorides are quite different. More urine is passed at night than during the day, but the differences are not as marked as in kidney disease. There exists a nocturnal polyuria and a diurnal polychloruria. Induced polyuria is often a valuable test in excluding organic disease.

Phylogenetic Significance of Spastic Paralysis.—Foerster, the chief student of spastic paralysis and its surgical treatment appears to believe that these children relapse into an atavistic state, as far as motor activities are concerned. Many comparisons of afflicted children and the anthropoid apes show strong postural resemblances. The positions in the children show marked analogies with the climbing posture of the apes. Thus in both the legs are flexed, feet supinated, toes flexed, abduction of the upper arms, etc., etc. In brief, the innervation current which in spastic paralysis proceeds from the subcortical centers and grey matter of the spine to the muscles, thereby causing the contractures, moves the same muscles which are innervated in the ape in the quiescent climbing posture.

July 8, 1913.

Extraction of Foreign Bodies from Children's Lungs.—Sehrt considers the entire subject in a case history. A child had inhaled a portion of a whistle, shown by the *x*-ray to have lodged in a main bronchus. There was not much suffering associated, although it was clearly indicated to remove the object at once. The boy was fragile, six years of age, and without the presence of authority to transfer him from the throat clinic to the surgical wards. Professor Kraske, as surgeon in charge, authorized the author to operate. A tracheotomia superior was first done, and the tracheal mucosa anesthetized with cocaine. Brüning's electroscope was then introduced into the trachea—the patient being under chloroform narcosis—and the foreign body accurately located. Efforts to remove it with Brüning's needle forceps failed. More chloroform and more cocaine were applied. The foreign body was then liberated, and extracted with Pfeiffer's forceps. The question of superior or inferior bronchoscopy is a subject of vivid discussion. Superior bronchoscopy through natural passages must only too often be followed by tracheotomy. The author insists that at the present time, when there is the least suspicion of status thymicolymphaticus or thyroid anomaly, tracheotomy with inferior bronchoscopy should be the method of choice. It is not a question of "operative elegance" in extraction, but of warding off certain causes of death.

Syphilis and Tuberculosis in German Southwest Africa.—Scherer found that in the interior of German Southwest Africa tuberculosis does not exist; but if consumptives do sojourn there the result is unfavorable. A "coast tuberculosis" does not exist. In the strains of aborigines known as Ovambo and Bushmen syphilis has never been diffused to any notable extent. Both syphilis and tuberculosis have been diffused by commerce and travel. Into the German coast the two diseases have been smuggled, syphilis doubtless from the marine ports, tuberculosis from the Cape region.

Relation of Colipyelitis to Fecundity.—Mayer refers chiefly to females as he is using the material of Sellheim's clinic. He appears to have reached no definite conclusions because of the coexistence of other factors. Nevertheless some strong affiliations have been brought out. There is in fact a coli puerperium which may end in various ways, and there is a coli infection starting in the nongravid under a variety of circumstances. These seldom seem to be typical but paradoxical and cropping out most unexpectedly. Because of the presence of the *B. coli* at the vulva, it is advisable to refrain from digital examinations during labor. It is also easy to cause propagation of the *B. coli* upward into the kidney by straining at stool compressing the ureter. Colipyelitis may also simulate peritonitis and cases are known in which the pus in a kidney pelvis has ruptured into the peritoneum. Again the pressure of the diaphragm on a colipyelitis might suggest a pneumonia. In fact, we sometimes have to decide between pneumonia, puerperal fever, appendicitis, and pyelitis. Finally pyelitis in pregnancy may simulate uterine hemorrhage. The general inference is that the occurrence of suppurative pyelitis resulting from colon bacillus infection is inimical to conception and may interfere with the normal course of pregnancy.

Can Cancer Heal Spontaneously?—Theilhaber quotes von Hansemann as stating that two kinds of cancer can heal spontaneously, to wit: chorioepithelioma and epithelioma of the face. Of course, it can be stated that these growths are not true cancer; but it has further been claimed that individual cancers of the uterus have never reappeared after simple means of treatment. In regard to modern teachings the author does not believe in the alleged radium, *x*-ray, and mesothorium treatment as curative; for common sense assures us that of the millions of cancer cells attacked by the rays, by no means all can be influenced. The beneficent influence of the destruction of hosts of cells is doubtless due, not so much to the crippling of tumor cells as to the stimulation of the connective cells. Any arrest of cancer growth he believes to be due to the latter cause which may hinder and sometimes prevent the cancer elements. Very recently C. Müller following out the author's suggestions brought about a cure or arrest of twenty cases of cancer of the breast. All available resources were applied and up to the present time not a single case of relapse was in evidence.

Quinine Ointment and the Prophylaxis of Syphilis.—Schereschewsky refers to the history of this phase of prophylaxis. In 1909 a 40 per cent. quinine ointment had been recommended. The method worked out completely in animal experiment. A series of apes inoculated with syphilis was quickly submitted to quinine ointment frictions before chancre could develop. The results on the whole were very favorable and no specific lesions appeared. The author, making no reference to calomel frictions, expresses his belief that the use of quinine should be of great value in the prevention of venereal diseases in prostitutes, soldiers, etc.

An "Error of Sex."—Zurhelle relates a case which is of interest because of the legal component in fixing the status of the sex of the individual. The subject was a "woman"—with a male habitus—who had been married twice and had been a widow for 5 years. She had never menstruated. Now at the age of 57 she showed more mannish traits than on any previous occasion, including a chin beard. Her hand and wrists were large and bony. The shoulders were masculine, while the genitals showed the ordinary penoscrotal hypospadias. Testicles and epididymi were plainly palpable. There was no evidence of a vagina or of uterus or ovaries. Both her husbands had been very well satisfied with her as wife, perhaps because she was a great worker. There was, of course, no issue nor was any desired. The "woman," on her part, was attracted by womanly females. The constituted authorities pronounced the subject a male legally.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

Adapting the Policy.—(The first part of this contribution appeared in MEDICAL RECORD, July 12.)

Ordinary Life Policies.—In this class the premiums are paid during the entire life of the policyholder and are calculated upon the entire mortality from the age at which the insurance is put into force. This policy is adapted to the individual who wants protection for the whole life at the least possible average annual cost during life. The policyholder receives his portion when the surplus is distributed at stated intervals and may elect to draw the dividend in cash, apply the dividend toward paying the premium, apply the dividend to the purchase of a paid-up addition to the policy, or let the dividend accumulate at the rate of interest assumed by the company in building up its reserve.

When the premiums for at least three full years have been paid, there is a stated loan and cash value. Furthermore, in the event of default of the premium, after the premiums for three full years have been paid, and there is no loan thereon, the policy will usually be automatically continued for the full amount insured, non-participating and without right to loans, for a definite period stated in the policy.

Limited Payment Life Policies.—The premiums are based upon the same data as in the ordinary life, but are arranged so as to be paid within a limited number of years, usually ten, fifteen, or twenty, instead of being distributed through the entire life. At the end of the stated period the policy becomes paid-up: *i.e.* although it still remains in force and the face value will not be paid until death, no more premiums will be called for. The holder of this form of policy has all the privileges that go with the ordinary life policy. He necessarily has to pay a larger premium but is entitled to a correspondingly larger amount of cash or paid-up insurance than in the case of an ordinary life.

This policy enjoys a well-earned popularity, for the holder pays up all his premiums during his younger and active days and may enjoy an ease of mind through the possession of a considerable amount of paid-up insurance for protection purposes on arriving at the age when care and stress should be things of the past.

Endowment Policy.—This policy is for a term of years and the premiums are based upon the mortality of those years, not of the entire life. It is, like the life policy, payable at death but has a further provision that the face amount shall be payable to the insured himself while living, if he survives a certain period, usually stated as either ten, fifteen, or twenty years.

The privileges are similar to those in the life plans with the exception that any additional insurance bought with dividends, or any extended insurance in case of lapse must terminate at the end of the period named in the contract.

This form of policy is suitable for the person who can spare a considerable part of his income for protection purposes and, at the same time, for a safe, sound and conservative investment.

Continuous Instalment or Life Income Policy.—This policy provides for an annual income after the death of the insured for twenty years certain, and for so much longer as the original beneficiary may live.

If the beneficiary dies within the twenty years the income for the remainder of the twenty years will be paid to the person or persons named by the original beneficiary, or one sum equal to the commuted value may be taken if preferred. If the beneficiary dies before the insured, the future premiums are rearranged on the basis of an ordinary life or limited payment life policy, according to form of contract, for an amount of insurance equal to the value of the life income policy or one sum equal to the commuted value may be withdrawn.

The object of this form of policy is to assure absolute protection to dependents and to prevent the early loss or dissipation of funds left to women and children who have no experience or business training. A too frequent event is the loss of such a fund through ill-advised investments, speculation, or extravagance of the beneficiaries. A multitude of advisers almost invariably appear whenever some person, especially a woman, inherits an estate and as a result of their interested or disinterested efforts, as the case may be, the proceeds of many an insurance policy, which has, perhaps, been maintained through a lifetime of toil and self-denial on the part of the husband or father, have been swept away.

By means of the continuous instalment or life income policy the insured may provide the dependents with absolute protection which the latter cannot frustrate. The beneficiaries will, furthermore, not have the care or worry incident to the investment of money, and will have an assured income as long as they live. They may waste one instalment but there will be another next year which cannot be anticipated or discounted in advance.

The Ideal Medical Director.—Mr. T. W. Vardell, president Southwestern Life Insurance Company, Dallas, Texas., pictures the ideal medical director as a man who is able to select the risks properly—one who has the ability to decline risks as well as issue the business. The medical director who, when he declines a risk, and it is on such grounds that full information cannot be given the agent, does it in such a manner that the agent appreciates what he has done—that man comes pretty near the ideal medical director.—Medical Section, American Life Convention.

Conservation of Public Health and the Insurance Companies.—Dr. W. A. Peterson, Medical Director Scandia Life Insurance Company, Chicago, holds the opinion that it is outside the province of the insurance company to carry the work of health conservation to the extent of invading the home of the individual in order to regulate health matters. He considers that the medical director of a company should devote his time to medical selection for life insurance, and that he is not the proper person to direct public health; a practical physician is needed for that work, and medical directors cannot well do both. Another point, many people belong to various companies, and if all companies were looking after the health of the same families, there might be an overproduction of good will towards men. He considers that the insurance companies are trying to do too much along these lines. Conservation is good, but it should be studied carefully before insurance companies undertake work which may not belong rightfully to them.—Medical Section, American Life Convention.

Book Reviews.

Les stenoses inflammatoires, chroniques de la region cardiaque de l'oesophage. By Dr. Georges Riebault, former interne of Paris hospitals. Bordeaux: Gounouilhon, 1913.

This book is divided into two parts, dealing respectively with anatomy and pathology. As to the first the author describes the intraabdominal part of the esophagus and speaks rather of it than of a "cardiac end" playing a separate rôle. There are numerous good diagrams and cross sections. Under pathology he discusses "those stenoses which are not neoplastic or traumatic or acute." Symptoms, prognosis, treatment are given and observations of some 27 cases are added, mostly from the literature.

The Carrier Problem in Infectious Diseases. By J. C. G. Ledingham, M.B., D.Sc., Chief Bacteriologist, Lister Institute of Preventive Medicine, London; Reader in Bacteriology, University of London; and J. A. Arkwright, M.D., Assistant-Bacteriologist, Lister Institute of Preventive Medicine, London. Price, $3.50 net. London: Edward Arnold; New York: Longmans, Green & Co., 1912.

This is one of the most recent and important of the International Medical Monographs edited by Leonard Hill and William Bulloch, and although it has been out less than a year, the work of Ledingham and Arkwright is generally recognized as an authority on the subject of the carrier problem in infectious diseases. The importance of the control of the disease carrier as a factor in efficient sanitary administration is gaining recognition every day. The authors present all the known data on this subject with reference to the following diseases: typhoid fever, paratyphoid fever and the infections caused by organisms of the Gaertner-paratyphoid group, diphtheria, epidemic cerebrospinal meningitis, dysentery, and cholera. One hundred and thirty-five pages are devoted to the problem of the carrier in typhoid fever: this liberal allotment is justified by the overwhelming evidence of the epidemiological rôle of the typhoid carrier. Following a historical review the authors discuss the general facts regarding typhoid carriers, their types, classification, age, sex, frequency, etc.; they cite instances of the infectivity of carriers, of milk-borne cases, of institutional cases, and of army carriers; they discuss the pathogenesis of the typhoid carrying state with particular reference to the intestinal carrier; they also point out the important relation between carriers and gallstone disease, and discuss the physical disabilities of the carrier state including the subject of autoinfection. The treatment of typhoid carriers, a vexing problem in sanitary administration, is gone into at length. The treatment includes chemotherapy, sour milk therapy, surgical treatment (as the removal of the gall-bladder), and vaccine therapy. The fact is deplored that as yet the attempts to cure intestinal carriers have as yet failed to yield convincing evidence of their success. Various other aspects of the typhoid carrier problem are fully discussed, including diagnostic methods, the infectivity of the carrier, immunity questions, and administrative measures. The desirability of the future enactment of legislative measures in the control of carriers engaged in the handling and sale of foodstuffs is emphasized. A complete bibliography is appended to this section. The rest of the volume follows out this comprehensive method. The book is a mine of information, gathered from many sources, and interpreted by those who have had practical experience in facing the many problems.

Bovine Tuberculosis and Its Control. By Veranus Alva Moore, B.S.M.D., V.M.D., Professor of Comparative Pathology, Bacteriology, and Meat Inspection, New York State Veterinary College at Cornell University, and Director of the College. Thirty full page illustrations. Price $2.00 net. Ithaca, N. Y.: Carpenter & Company, 1913.

The subject of bovine tuberculosis is one that has justly attracted considerable attention within recent years, particularly since it touches so many interests, the farming and the dairy industries, the medical profession, public health authorities, and, most important of all, the public itself. The economic loss alone in the United States is $14,000,000 annually. It is therefore gratifying to note the appearance of a volume that sums up all modern knowledge upon this subject. No one is more competent to write upon bovine tuberculosis than Professor Moore, who devoted many years to its study and who has made substantial contributions to its experimental investigation. The scope of this volume is amply indicated by its chapter headings, which are as follows: history of tuberculosis in cattle; distribution, economic and sanitary importance of bovine tuberculosis; the cause of tuberculosis in cattle; the nature of tuberculosis and the changes produced in the tissues by tubercle bacteria; symptoms of tuberculosis in cattle; methods of dissemination; the diagnosis of tuberculosis in cattle; tuberculin and its use; physical examination in detecting tuberculosis in cattle; immunization of cattle against tuberculosis; the control of bovine tuberculosis; and report of the International Commission on the Control of Bovine Tuberculosis. Of considerable interest is the chapter on the diagnostic use of tuberculin. It is pointed out that infected cattle do not react when the disease is in the period of incubation, when it is arrested, and in certain cases where the disease is very far advanced. According to Carin 17 per cent. of infected cattle fail to react. This percentage is larger than the author's experience indicates. The various methods of controlling bovine tuberculosis are fully described. The report of the International Commission on the Control of Bovine Tuberculosis is given in detail. This report is found to meet the conditions as they prevail in America. When it is understood that 10 per cent. of the dairy cattle of the country are infected the extent of the problem of eradicating the disease may be fully realized. According to Moore the secret of accomplishing this control is to prevent the spread of tubercle bacteria from the present infected cattle. At present there is no successful method of immunization. The author has written a book of eminently practical value to the veterinarian and to the physician. There are appended to the volume thirty full-page plates illustrating the different phases of tuberculosis in cattle and cultures of tubercle bacilli. These plates are superb in their artistic execution.

Die Tabes der Frauen. Von Kurt Mendel und Ernst Tobias, in Berlin. Preis 2.50 M. Berlin: S. Karger, 1912.

This is a monograph of 70 pages containing much that is of interest and value. Statistics as to the frequency of tabes in women are very variable. The statistics of this monograph are based on 163 cases, 12 only in private practice. The 151 clinic cases occurred at the same time as 279 cases among the men, making the percentage as 1 to 1.85. Sterility among the women was five times as high as among normal women. The important question of the relation of syphilis to tabes is fully discussed. The symptoms of tabes in men and women are compared. The incubation period of tabes is stated to be shorter where an underlying syphilis has been treated than when it has remained untreated especially by mercury. Other interesting facts are brought out respecting crises, complications, etc.

Minor Maladies and Their Treatment. By Leonard Williams, M.D., M.R.C.P., Physician to the French Hospital; Physician to the Metropolitan Hospital; Late Assistant Physician to the German Hospital; and Hon. Medical Officer to the Sidmouth Cottage Hospital. Third Edition. Price $2.50 net. New York: William Wood & Company, 1913.

Minor maladies still constitute the great bulk of all human ailments, and a book such as this, which in its two previous editions has achieved a wide popularity, cannot but fill a distinct gap in medical literature. The lesser complaints of humanity are accorded scant attention in the regular textbooks, and are dealt with in a stepmotherly fashion by the majority of medical teachers. The result of this pedagogical neglect is that many practitioners know little more about the treatment of such common disorders as indigestion than the average layman. The scope of this book may be gleaned from an enumeration of the chapter headings: colds, coughs, and sore throats; indigestion; constipation, diarrhea; vomiting, and giddiness; rheumatism, neuralgia, headache; goutiness; change of air; general health; some drugs, and their uses; and insanity. Goutiness is not a common disorder in this country, nor is insanity as common as some would have us believe. At any rate it is difficult to conceive insanity as a minor malady. The author admits this fact, but includes the subject of insanity because the ordinary text-book on medicine gives but scant attention to the practical phases of this subject. The book is admirably written, and the practitioner will find in it a great deal that will help him in his daily work. It contains a large number of useful prescriptions. Among some of the subjects that are fully discussed may be mentioned the following: hiccough, flatulence, and seasickness. The chapter on change of air contains a good deal of information on the subject of European watering places. A perusal of the chapter entitled "Some Drugs and Their Uses" ought to prove an efficient antidote to therapeutic nihilism.

Society Reports.

THE AMERICAN GYNECOLOGICAL SOCIETY.

Thirty-eighth Annual Meeting, Held at Washington, D. C., May 6, 7, and 8, 1913.

THE PRESIDENT, DR. HENRY C. COE OF NEW YORK, IN THE CHAIR.

Uterine Inertia; Its Treatment.—DR. GEORGE TUCKER HARRISON of Charlottesville, Va., said that when the uterine muscle showed feebleness in the beginning of labor and during dilatation this condition of atomy was called primary uterine inertia. The cause may be due either to anatomical changes in the uterine muscle or in disturbed innervation. Secondary inertia was a condition of exhaustion which came on during the period of expulsion from various causes. Before rupture of the membranes in primary inertia there was no indication for active intervention. After rupture, if there was danger to life of the child from the discharge of liquor amnii, or the mother's life was imperiled from danger of septic infection, dilatation should be brought about by the metreurynter (rubber bag) version followed by extraction then being employed. In secondary inertia a too protracted labor was dangerous to the mother and child, active intervention was indicated; if the head was well down in the pelvis and resting upon the perineum, the forceps was applied. It had been recently proposed to perform Cesarean section in certain cases of uterine inertia, especially in the interests of the mother. The obstetric resources at our command were amply adequate, and there was no indication for such operative procedure in inertia *per se*. In primary inertia a combination of morphine, atropine, and strychnine often had an excellent effect when given hypodermically. After dilatation pituitary extract had found favor with some obstetricians.

Pituitary Extract in Uterine Inertia.—Dr. J. CLIFTON EDGAR of New York City reported 70 cases of which records had been kept, and these cases were from two hospital services, namely, Bellevue and Manhattan Maternity and from private practice. They included in the first and second stages of labor, 39 cases; immediately after the third stage, 19 cases; in Cesarean section, 6 cases, and for the induction of abortion, 6 cases. He drew the following conclusions: 1. Ampoules or vaporoles of the drug should alone be employed, as in his experience, constant results failed when the pituitary extract in bulk solution was used. 2. There were three reliable proprietary preparations of the drug now on the market; all of these were used at different periods in his cases. 3. For decided action, 0.4 gram of the drug was usually called for, although in ordinary cases, with little obstruction, half that dose was found sufficient. 4. As the effect of the drug lasted but 30 minutes, repetition of the dose was often called for. 5. Intramuscular injection was usually satisfactory; causing no local reaction or pain. Further, no toxic symptoms were observed from the use of the drug even in maximum doses. 6. Pituitary extract might be combined with ergot when the action of the former failed, and with heart stimulants in shock cases, without compromising the actions of these drugs. 7. Pituitary extract had no place in normal labor, the administration should be confined in obstetrics to instances of primary and secondary inertia, to postpartum hemorrhage and cesarean section, in the last as a substitute for ergot. 8. The drug produced strong intermittent uterine contractions often prolonged for several minutes. He had never observed true continuous tetanic uterine contractions (tetanus uteri). 9. Although theoretically the uterine contractions were intermittent, practically in the face of resistance, the contractions approached to the continuous in character and clinically might be so reckoned with. 10. Full and even small doses of the drug in the first stage of labor had caused in his cases fatal compression of the fetus, premature separation of the placenta and deep rupture of the cervix. 11. In the first stage or where some obstruction existed in the second stage, he gave small tentative doses of pituitary extract, not with complete delivery by means of the drug in view, but to bring the head in easy reach of a simple forceps operation. Seven of his 39 cases were thus treated. 12. Pituitary extract acted promptly and efficiently in most of the 39 cases of inertia in the second and first stages. Its actions were more positive in multiparæ than in primiparæ; it acted better at full term than in premature cases; also better in the second than first stage of labor, and when administered shortly after the spontaneous artificial rupture of the membranes.

In 18 postpartum cases he found no effect of the diately after the third stage for postpartum hemorrhage due to inertia, his results were disappointing. So much so that he considered its action here most unreliable and not as positive as the ergot preparations.

In the 18 cases in which the drug had been used, immedrug in two cases; it was necessary to use ergot in two instances; hot acetic acid douche in two more; to pack the uterus in seven cases, and in the remaining six cases only were good uterine contractions observed. 13. In Cesarean section he could not observe any advantage of pituitary extract over ergot, aside from the observation that the former acted more promptly and hence need not have been administered so early in the operation. 14. In induction of labor the drug failed to initiate contractions, but apparently initiated them after the use of gauze, the bougie or hydrostatic bag for inducing labor. His belief was the drug strengthened already existing contractions not yet apparent to patient or physician. 15. For primary inertia in abortion cases, his results with the drug were disappointing. 16. For atony of the bowel and bladder and as a galactagogue his results were frankly negative. 17. The dangers to mother and child in the indiscriminate administration of this drug for primary or secondary inertia of the first or second stage of labor must be reckoned with.

Only a few of his 39 cases of inertia were frankly in the first stage of labor and these were earlier cases. The remainder were of the second stage or borderline cases just merging into the second stage.

He considered the use of the drug in the first stage a dangerous practice, liable to cause death or deep asphyxia of the fetus, separation of the placenta, uncalled-for laceration of the cervix and possible uterine rupture.

18. He had to report of his 39 cases of inertia in the first and second stages two and probably four stillborn children due, in his opinion, to the use of pituitary extract, before full dilatation, and three instances of deep laceration of the cervix requiring suture to control the bleeding. 19. He looked upon the use of pituitary extract before full dilatation or dilatability of the cervix as equivalent to the use of ergot at this time. In fact, it was probably more harmful than ergot, by reason of the more powerful contractions produced, and the uncertainty of it action. 20. He had repeatedly observed prolonged tempestuous contractions when the drug was given in the face of too much resistance, closely simulating tetanic contractions of the uterus (tetanus uteri). 21. The action of the drug was most uncertain. One could never predict in a given case, either from the amount of the drug administered or from the character of inertia and the obstruction to be overcome how powerfully the drug would act upon the uterus. 22. He had repeatedly observed both in private and hospital practice that 0.2 gram of pituitary extract, half the usual dose commonly employed, produced such prolonged and powerful uterine contractions that uterine rupture was imminent and anesthesia was required to control the action of the drug on the uterus. 23. In his opinion the drug should never be employed for inertia in any stage of labor, unless anesthesia was at hand for immediate use and preparations were complete for immediate operative delivery, if necessary, to avoid uterine rupture. 24. Finally, with due regard to its action and possible dangers, pituitary extract was a most valuable addition to the resources for the treatment of primary and secondary inertia.

Under What Conditions Should Uterine Inertia Be Treated by Artificial Delivery?—Dr. EDWIN B. CRAGIN of New York City said uterine inertia was of greater importance in the second stage of labor, especially if the membranes were ruptured and the pressure of the uterus came directly upon the child than in the first stage, yet in several cesarean sections performed during a prolonged first case the presence of meconium in the liquor amnii and the marked slowing of the fetal heart prior to the operation had convinced him of danger to the fetus from uterine inertia even during the first stage of labor.

Uterine inertia associated with fetal heart sounds indicating danger to fetal life was one of the first types of inertia indicating artificial delivery. His plea was for studied, skilled, artificial assistance in the delivery before the mother and child were exposed to these dangers.

There was one condition not usually classed as uterine inertia which the writer called attention to before closing his paper. It was the long delay which sometimes intervened between the rupture of the membranes and the uterine contractions of the first stage of labor. Patients sometimes presented themselves at the hospital with a history that their membranes had ruptured, three, four, or

even five days before their labor began. An unfortunate experience several years ago in which the fetal heart ceased before the labor was completed, and a study of the temperature charts of a number of these cases convinced him that in many particulars they resembled cases of uterine inertia during actual labor; that there was fetal danger from interference with fetal circulation from prolonged pressure and that maternal morbidity was common from sapremia, if not from bacteriemia. For these reasons he had made it a rule in recent years, both at the Sloane Hospital and in his private practice, to introduce an elastic bag into the cervix if uterine contractions had not started at the end of 24 hours from the time of the rupture of the membranes. The elastic bag, as a rule, not only brought on uterine contractions, but lessened the further escape of the liquor amnii, and the results both fetal and maternal had seemed to justify the procedure.

Dr. Edward P. Davis of Philadelphia stated that from the accumulated experience of the profession it seemed pituitrin came into practical competition with strychnine, opium, and ergot, and Dr. Edgar had given a very valuable hint as to the danger of pituitrin. We all recognized the fact that in many cases opium to the point of lessening nervous excitability and securing rest was of the greatest value in bringing about the development of the physiology of labor, and we were all aware of the very frequent experience of the unexpected and rapid delivery of multiparæ, to whom we had given opium to secure rest, and how frequently the woman surprised herself and us most of all when we were caught napping, but certain was opium in the general experience of the profession was the one sedative which was a stimulant to the ganglion which controlled the action of the uterus.

As regards strychnine in comparison with pituitrin it seemed to him the difference between the two might be stated in this way, that strychnine, given in moderate doses was a physiological stimulus to the ganglion supporting and maintaining uterine action, while pituitrin, and especially as indicated by Dr. Edgar, was a matter of more brief and more stormy result, and hence much more uncertain, and personally he had not felt that he could substitute pituitrin for the use of strychnia as a physiological stimulant or aid in labor.

The use of ergot was a thing to be carried out with great caution, aand he still adhered to the belief that ergot should be given upon the emptied uterus only, and in Cesarean section one might lay aside ergot entirely, oftentimes with advantage.

As to contracting the dilating bag with the bougie as an inducer and promotor of labor in connection with strychnia or pituitrin, it was of advantage in that it decidedly stimulated the mucous secretion of the cervix and was less apt to alter the mechanism of labor.

Dr. John O. Polak of Brooklyn, N. Y., stated that no discussion of pituitrin in this society should go out without sounding a word or two of warning. He had had within the last three weeks a case of rupture of the uterus from the use of pituitrin. He had also seen within a month a case that was thrown into such violent uterine contraction that anesthesia and morphine had to be used to control the spasm of the uterus; consequently from his experience, which was comparatively limited, only 76 cases, he had drawn some conclusions that were only tentative, that pituitrin had little or no place in the first stage of labor; that it was dangerous so far as one's experience was concerned unless there was absolute knowledge of the pelvis, particularly in outlet contractions and particularly in borderline contractions.

Furthermore, in order to get the best use from pituitrin there should be a dilated or at least a dilatable cervix, because injuries to the cervix had been just as Dr. Edgar had stated. He had found, furthermore, that it had no value, as far as his limited experience had gone, in establishing uterine contraction, in emptying the uterus in cases of incomplete abortion.

Another observation he had made was that where it was used in the third stage of labor, he had gotten secondary relaxation in a sufficient number of cases to warn him that when he used it in the third stage it should be combined with ergot.

Dr. Henry T. Byford of Chicago stated there was a mild form of inertia which in primaparæ meant a great deal perhaps in some cases, due to general exhaustion from muscular exercise of the prolonged first stage, or want of rest and exhaustion of the nervous system. He had seen many cases in which there was inertia of the cervix. The patient had an irritable condition of the parts and would have if the first stage of labor was unusual in its length. At one time, when investigating the function of the membranes in labor with a view to preserving them, he got in the habit of using opium frequently, and in these cases the administration of opium would give rest, particularly as it acts in contrast to the advice so often given to women to get around and try to stimulate labor.

Dr. Robert L. Dickinson of Brooklyn, N. Y., said that between foreign and American obstetrics there was one great distinction. Dr. Kerr read a very able paper before this society on waiting or long delay in the second stage of labor. The German practice of delay in the use of the forceps or the infrequent use of the forceps as compared with the American was most striking. He believed the particular type of American woman, neurotic, easily tired from vigorous muscular exercise and anxiety, was a type to which the pituitary extract particularly applied. It was most fortunate to have had so lucid an exposition of the exact therapy of pituitary extract as Dr. Edgar had given.

Dr. William E. Studdiford of New York City said one of the most important points in these three papers was that of calling attention to the dangers of pituitary extract. Enthusiastic reports sent around by the manufacturers led to the promiscuous use of pituitary extract with many unfavorable results. His own experience had been very much the same as that of Dr. Edgar. The pituitary extract was so uncertain in its action in the first stage of labor that it was apt to cause such bad results in the cervix that the cervix, it seemed to him, should either be fully dilated or dilatable, and was many times, but where the diagnosis was positive that there was no obstruction to rapid delivery, delivery could be brought about promptly. Therefore, the question of diagnosis was important in the management of these cases as well as the indication for treatment. An accurate diagnosis should be made before any line of treatment was followed out.

Dr. Charles M. Green of Boston stated that these radical papers were going out to influence general practitioners, and in the subsequent discussion something ought to be said as to what should be done in the way of prevention of uterine inertia. The average woman who was going to have a baby should be trained to go through the ordeal just as a good athletic trainer would teach men on a football team. We should train her for the condition, and if this was done in a large proportion of cases the inertia would disappear. Furthermore, there were a great many women who were benefited during the last two months of pregnancy by systematic treatment with iron, arsenic and strychnia. He gave strychnia in small doses to women in the last two months of pregnancy. If a woman was in pretty good shape physically, was not tired, if she had a fair nervous system, she would go through labor pretty well if she kept moving around.

Dr. J. Clarence Webster of Chicago said that in cases of uterine inertia associated with rigid, elongated, or hypertrophied cervix, he believed that the important measure of treatment was vaginal Cesarean section, and not abdominal Cesarean section unless there was contraction of the pelvic outlet.

As regards the use of pituitrin, he had been using it in the Presbyterian Hospital, Chicago, and his experience harmonized with that of Dr. Edgar, although he had not used it perhaps in as many cases as he had.

Demonstration of the Infant Pulmotor, with Remarks on Its Use in the Treatment of Asphyxia Neonatorum.—Dr. Henry D. Fry of Washington, D. C., said the introduction of the infant pulmotor into obstetric practice was so recent that he had not been able to collect any statistics of the value of the apparatus. Certainly it was vastly superior for resuscitation to the ordinary methods of artificial respiration. He had had no opportunity to test it in a serious form of asphyxia, the so-called asphyxia pallida, but in the livid form it had acted promptly and resuscitated the infant in about 5 minutes. Edgar said he had used the apparatus six or seven times in both asphyxia pallida and livida. The results were good, much better than he had anticipated because, at first, he was doubtful of the value of the apparatus. Communication from Rochester reported the use of the pulmotor in five cases. In Case II. it was unsuccessful. There was no heart action detected when the infant was born. In Case IV. it was likewise unsuccessful but there was no mention of the heart action. In Case I. the infant was born with marked asphyxia, but cardiac pulsations were detected. The labor had been prolonged but was terminated by midforcep application. The ordinary methods of resuscitation

were employed for 10 minutes without results. The pulmotor restored life in 10 minutes and the infant lived. Case III.—Pronounced asphyxia of the infant with heart action. After failure to resuscitate the infant breathed after 3 or 4 minutes of the application of the apparatus. Case V.—A labor of 30 or 40 hours duration was terminated by a difficult, high-forcep application. The infant had deformities of the extremities and had been born 30 minutes before the use of the pulmotor. The heart action was slow, 80 to 90 per minute. After 40 to 60 minutes' use of the pulmotor the infant breathed but died 2 hours afterward. The condition of the infant suggested strongly the existence of intracranial pressure.

Efforts to resuscitate the infant should not be abandoned as long as there was any heart action.

Dr. James C. Edgar of New York City stated that he believed he had the first infant Draeger pulmotor that came into this country. It was more than a year ago. At first he looked upon the machine with more or less skepticism, thinking it was more of a plaything than anything else, but having used it for some time he found there was some value to it. They had one at the Manhattan Maternity which was ready for use in every operative case. They had had several cases which illustrated the value of the machine, but as Dr. Fry had said, the inspiratory force should not be run up to 25. He thought 10 or 12 cm of force was sufficiently high. Although he had made no autopsies to prove it, he believed there was some likelihood of rupture of vessels when they ran the inspiratory force up to more than 10 or 12 cm.

Dr. John O. Polak of Brooklyn stated that he would like to ask Dr. Fry if the pulmotor could be attached to the ordinary oxygen tank in case of emergency.

Dr. Fry said they had an extra attachment so that it could be put on an ordinary oxygen tank.

Factors in the Formation of Skin Striations During Pregnancy.—Dr. Frederick J. Taussig of St. Louis, Mo., said only thirteen out of sixty primiparæ were free of skin striations. Skin striations occurred most frequently at several points and usually made their first appearance about the sixth or seventh month of gestation. In girls under 20 years of age they were decidedly more pronounced and more frequently found than in older women. Obesity, particularly rapid increase in weight during pregnancy, predisposed to the formation of striæ, especially those about the breast and thighs. Lack of abdominal support during pregnancy, as in those who wear no corsets, favored the formation of abdominal striæ. On the other hand, the tense and inelastic skin in which such striæ were found was to some extent a factor in subsequent abdominal relaxation. At any rate, abdominal muscular relaxation and abdominal skin striation went hand in hand. Perineal tears had apparently no relationship to skin striation. Finally the persistent employment of proper skin massage would, in the great majority of cases, prevent the formation of the slightest skin striations.

Uterine Carcinoma; Another Hypothesis as to Its Cause and Prevention.—Dr. A. F. A. King of Washington, D. C., spoke first of having converted the somatic epithelial cells into reproductive cells by abnormally rapid cell proliferation produced by continued irritation. Second, he referred to the fertilization of these transformed cells by spermatozoa. Third, of the pseudoembryonic structures of cancer produced by segmentation of these fertilized epithelial cells. Fourth, clinical facts and observations were advanced in support of the hypothesis. Speaking of prevention he said that there should be an avoidance of contact of the sperm with irritated, senescent tissue. Finally, he considered the question of whether we should amputate the cervix before cancer and whether or not we should advise against marriage after the menopause.

The Menace of Cancer.—Mr. Frederick Hoffman, statistician of the Prudential Insurance Company of America, gave an address on this subject in which he summarized the results of his investigation as follows: On the basis of trustworthy official data it was safe to estimate the annual mortality from cancer in the United States as 75,000 and in the civilized world at half a million. The cancer death rate in the United States was increasing at the rate of 2½ per cent. per annum and a corresponding increase was taking place practically throughout the civilized world. The average age of death cancer in all forms was 59 years, or respectively 60.4 years for males and 58.2 for females. Cancer was largely a disease of adult life and of the total mortality from cancer, 90.7 per cent. were deaths of ages of 40 and over. The male cancer death rate in the United States, ages 25 and over, had increased 29 per cent. during the last decade and the female cancer death rate had increased 23 per cent. On the basis of past experience the distribution of cancer deaths in the United States during 1913 would be about as follows: Cancer of the stomach and liver, 30,105; cancer of the female generative organs, 11,235; cancer of the rectum, intestines, and peritoneum, 9,608; cancer of the breast, 9,817; cancer of the mouth, tongue, etc., 2,880; cancer of the skin, 2,670, and cancers of other organs and parts, 11,685.

These statistics fully sustained the conclusion that cancer was a most serious menace to the American people and that the tendency was toward an increase in the mortality, regardless of the cancer deaths prevented by early surgical operation. The cancer death rate of large American cities had increased from 37.2 per 100,000 of population during the 5 years ending with 1876 to 80.5 during the 5 years ending with 1911. The cancer death rate of the City of New York had increased from 37.5 per 100,000 of population during the 3 years ending with 1872 to 81.4 during the 5 years ending with 1912. The corresponding increase in the cancer death rate of Philadelphia during the same period of time had been from 41.3 to 86.3. At ages 60 and over in the State of Massachusetts the mortality from cancer of the external organs for males had increased from a rate of 65.1 during the 5 years ending with 1910. The corresponding increase for females, ages 60 and over, had been from 85.6 to 122.3. Aside from the observed increase in the mortality from cancer, there had been an increase in the mortality from biliary calculi in the registration area of the United States from 1.5 per 100,000 of population in 1900 to 3.0 in 1911. All the facts available for the different sections of the country and the principal cities throughout the world sustained the conclusion without qualification, that the menace of cancer was much more serious at the present time than it had been in the past. Since, as far as known, the disease was invariably fatal unless the cancer was removed in its entirety in the very early stages of the disease by qualified operative treatment, it was obviously of the utmost importance that the elementary facts concerning cancer should be better known and understood than they were at the present time.

The only hope for the patient lay in the early possible recognition of the symptoms of cancer, when operative treatment was a comparatively easy matter, with a practical certainty of success. Neglect, on the other hand, was absolutely certain to result in death from one of the most awful conceivable afflictions, summed up in the following descriptive statement by one of America's foremost surgeons, who himself had saved a large number of valuable lives by early operative treatment. "To relieve the horrible sufferings of prolonged nausea, the intolerable distress of continuous vomiting, the excruciating pain, the keen distress of abdominal tension, the indescribable torture of protracted insomnia, the unparalleled agony of a living death, are all worthy of consideration."

The cancer problem as thus stated, emphatically suggested the intelligent coordination of all possible agencies for the control of what had properly been called a national scourge and the deliberate reduction of the death rate of what was stated to be a preventable disease when subjected to early operative treatment. There was, therefore, urgent need for a national society for the study and prevention of cancer, and it was a gratifying fact that such a society was in course of formation. Looking back over the results which had been achieved through the nation wide movement in the prevention of tuberculosis, there were strong reasons for believing that equally satisfactory results would, in the course of time, be secured in the prevention of cancer.

President's Address: Pathology the Basis of Gynecology.—Dr. Henry C. Coe of New York City said our knowledge of tubal disease had made rapid strides through the aid of bacteriology. The etiology and treatment of pelvic suppuration, so familiar to every medical student, had been long obscured by the famous pair-pelvic cellulitis and peritonitis. But however crude may have been the old pathology, we should not forget that the treatment was sound—to incise and drain a pelvic abscess through the vagina. When, with increasing boldness, they began to open the abdomen in acute inflammatory affections, they paid for their experience at a fearful cost. Even the general practice of drainage did not avail, and in fact they now know that probably the majority of the patients who recovered did so in spite of it. The necessary association of pain, of a so-called lancinating character, with internal malignant disease was an idea so firmly established, that it was difficult to eradicate it from the minds of the

profession as well as of the laity. How many women with cancer had been allowed to reach the inoperable stage because of the absence of this symptom they dared not conceive.

They were still in the dark as regards the etiology of various pelvic pains, when an opportunity was not afforded by exploratory section to verify our doubtful diagnosis of localized adhesions, twists of pedicles, minor degrees of systic and other chances in the ovary.

More intelligent study of the parametria had shown that many cases were rejected as unfavorable when the disease was really confined to the uterus, inflammatory exudate being mistaken for cancerous nodules. The limits of the radical operation had been greatly extended by Wertheim, whose experience and technical skill enabled him to deal with cases formerly regarded as inoperable.

We could not be indifferent to the earnest efforts of pathologists to discover the ultimate cause of cancer, and by careful experimentation to find a cure, either a serum or some metallic compound analogous to salvarsan. It could not be possible that the efforts of the many devoted workers in the laboratory would not eventually be crowned with success. While we pinned our faith at present to surgery, so far from any antagonism existing between the laboratory and the operating room was concerned, we were essentially inter-dependent.

Further Report of Cases of Dysmenorrhea Relieved by Nasal Treatment.—Dr. Joseph Brettauer of New York City, said after an experience of two and one-half years with the nasal treatment of dysmennorhea, the final results showed that in about one-half the number of cases so treated, the results were favorable. In some cases the benefit was temporary, requiring another course of nasal treatment. In other instances the relief was prompt and permanent after three or four caustic applications to the nasal spots during a menstrual interval.

In his paper he reported 66 cases so treated.

Dr. Emil Mayer of New York City stated it had been his privilege to see these cases reported by Dr. Brettauer, and also quite a number of others which he had not seen fit to include in his report, because he was not aware of some of the conditions presented. Some of these cases were patients of his own. In following out the treatment of these cases occasionally a young woman would come to his office with intranasal difficulty, and naturally being interested in the question of painful menstruation, he elicited from some of them that they had suffered a great deal, and following treatment of the nasal conditions he was able to benefit them, so that his own statistics which he hoped to publish later would be more favorable than those of Dr. Brettauer, although it must be said that he put his patients through a very severe test and did not accept his conclusions until he had seen the patients themselves.

As to amenorrhea, he had had several young girls who had not menstruated at all for three or four months, but after applications to the nose, menstruation became established.

Dr. E. C. Dudley of Chicago said he would like to ask if he understood the author of the paper to say that this cauterization treatment of the nose should be used in all cases in which there was neither pelvic nor nasal lesions? In other words, if examination of the pelvis and of the nasal passages was found negative, would he then empirically cauterize?

Dr. Henry T. Byford of Chicago stated one of the chief objections he had to this method was the indefiniteness in regard to the kind of dysmenorrhea and the condition of the nose. As he understood, there had been no study made of the kind of dysmenorrhea to be helped. There were no lesions of the nose except during the menstrual period, or when congestions appeared during their menstrual period, and they were usually regarded as a result, and not as a cause of something, and when women had pain in their breasts every month, we did not treat the breasts, thinking we would cure any disturbance in the pelvis. There were a good many kinds of dysmenorrhea, one of which had not been described, namely, nervous dysmenorrhea. He was willing to concede that the treatment outlined by Dr. Brettauer would help patients who had this form of dysmenorrhea.

Dr. Robert C. Myles of New York City said he found many cases of serious local irritation in the nose, where the central nervous system seemed to be in a state of aggravation or irritation as a result, with phenomena in other parts of the body being created, and when that irritation in the nose was relieved the other symptoms or phenomena disappeared.

Dr. W. Gill Wylie of New York City stated after a long study of this subject he had come to the conclusion that in many of these cases the underlying cause was imperfect development of the lining membrane of the uterus. A peculiar case came under his observation not long since. A mother brought her child to him. He asked her what was the trouble. She said that about the time of menstruation, or when it was approaching, her daughter could not appear in company, especially if there were gentlemen about, because suddenly her lips became so large and her face so red that she felt very uncomfortable and uneasy. He studied the case and told the mother he thought he could make a diagnosis. The girl was put on the table, with the mother and nurse present, and on examination he found little or no abnormal changes in the vulva except the girl was not fully developed. He did not detect any gross disease, but he noticed the secretions about the vulva became very profuse. He found when examining women, if there was a neurotic feeling that developed or arose, if he examined the cervix uteri or the condition of the uterus, there would be found marked changes in the erectile tissue.

Dr. Brettauer, in closing, said in answer to Dr. Dudley's question, he would say by all means touch the nose in the absence of any pathological condition in the nose and the pelvis. He would do so on an experiment, as it could do no harm.

The Conduct of Gynecological and Obstetrical Operations in the Presence of Acute or Chronic Endocarditis.—Dr. John Osborn Polak, Brooklyn, N. Y., said to summarize his experience in gynecological operations, he would conclude: 1. That pelvic conditions necessitating operation may be done after proper cardiac preparation. 2. That the cardiac symptoms, blood pressure and the functional activity of the liver and kidneys were the only indices of when it was time to operate. 3. That these cases should always be seen and treated in conjunction with a competent internist. 4. The operation should be rapid, bloodless, and done under combined local and general anesthesia, morphine, novocain, ether and oxygen. 5. That the Trendelenburg posture should be used only until such time as the field might be properly isolated, when the patient might be gently lowered out of it. 6. That phlebotomy should be done promptly on signs of right heart engorgement. 7. That postoperative distention must be avoided. 8. That morphine was the mainstay in therapeutics.

The Influence of Ectopic Pregnancy on the Blood Supply of the Uterus, with Special Reference to Uterine Bleeding: Based on the Study of 25 Injected Uteri Associated with Ectopic Pregnancy.—Dr. John A. Sampson of Albany, N. Y., stated that as a result of ectopic pregnancy the uterus was enlarged, due mainly to hyperemia and a thickening of the endometrium. The changes in the latter were similar to those found in the decidua vera of early uterine pregnancy and apparently due to its arterial invasion from the terminal branches of the radial artery. The venous spaces of the endometrium were dilated and this dilatation was most marked in the superficial portion of the compact layer and at its junction with the spongy layer. The termination of the pregnancy was followed by involution of the uterus.

The first step in the involution of the endometrium was seen in the greater dilatation of the venous spaces, probably due to regressive changes in the stroma and apparently dependent upon a diminished supply of arterial blood. The arteries were less evident during involution of the uterus. The dilatation of the venous spaces was followed by the escape of venous blood in the tissues of the endometrium. If the superficial venous stasis of the compact layer gave way, the blood would escape into the uterine cavity, without the formation of a decidual cast. On the other hand, if the venous spaces at the junction of the compact and spongy layer gave way, the extravasation of blood would occur mainly between these two layers and the compact layer would be expelled as a decidual cast. In time the regressive changes ceased and were followed by a reparative process which was apparently dependent upon the respiration of the arterial supply of the endometrium. The involution following the termination of tubal pregnancy was very similar to that following uterine pregnancy, differing only in degree.

In the vast majority of cases of ectopic pregnancy the complete termination of the pregnancy was a gradual process often taking several days or weeks, four weeks or more in seventeen of the twenty-five cases studied. When operated upon the uterus had been and might still receive stimuli from two distinct antagonistic sources, namely, pregnancy and involution. The condition present in any case depended upon which of these sources predom-

mated and to what extent it had been and was influenced by the other.

The uterine bleeding was of venous origin from the venous plexus of the endometrium due to regressive changes in the latter, apparently dependent upon a diminished arterial supply. Muscular insufficiency might also contribute to this. The bleeding continued as long as the pregnancy (products of conception) interfered with the process of involution. It was probably analogous to the bleeding in sub-involution of the uterus due to an incomplete uterine abortion.

Dr. Philander A. Harris of Paterson, N. J., said to one who had performed a good many operations for ectopic gestation, to be specific 228, it was interesting to have this unquestionable demonstration of the changes which occurred in the uterus. It would not have been possible for him to have exhibited uteri from the cases on which he had operated for ectopic gestation, excepting those uteri that were also the seat of some neoplasm or fibroid or something of that kind. This brought up the question of what practical use was the uterus after operating upon a patient for a single gestation? Dr. Smith of the Society collected a good deal of valuable information along this line, and he hoped he might be pardoned for saying he had not had time to find out how many women in the 228 operations for ectopic gestation really gave birth to children, but according to Dr. Smith and others the number was exceedingly small. There had been only four or five women who, after being operated for ectopic gestation, gave birth to children. Possibly there were four out of the 228 on which he operated. In thirteen of these the ectopic gestation was recurrent. The only point which came to his mind now was whether, in order to secure only four or five offsprings in possibly 228 cases, we should save the uterus, not sacrificing menstruation, for the little interest in future offsprings.

Dr. Hiram N. Vineberg of New York City said he would like to ask Dr. Sampson how he would explain those cases of uterine hemorrhage, so far as symptoms go, that had occurred probably before the termination of pregnancy? The first symptom might be uterine hemorrhage. Perhaps a day or two later the woman might have an abdominal cramp showing that tubal gestation had taken place. Probably it was digressing from the purpose of the paper in discussing the necessity of removing the uterus in such a large number of ectopic pregnancies, and it would not be in the trend of conservatism which we were trying to follow so as to retain menstruation and the ovaries in as many cases as we possible could. In a large number of cases he could only recall two instances in which he felt the condition was such that surgically it was necessary to remove the uterus. In the other cases the uterus was retained. He could recall at least six cases of normal pregancy following previous ectopic pregnancies.

Dr. Sampson in closing the discussion said in eleven cases of the series the uterus was retained when the opposite tube was examined, because the women wished to have children. In every case he talked over the possibility of children before operating. He had followed the future history of these eleven cases; five of them had not become pregnant, although in two of them only a few months had elapsed since the operation. Two had borne children, one two and the other one, and the one who had one child subsequently had tubal pregnancy in the opposite side. Three had had miscarriages, although they claimed they desired to have children. One had three miscarriages and the other two had one each. Another, the sixth one, had tubal pregnancy in the opposite side, making two cases of repeated tubal pregnancy in the eleven cases in which at the time of operation the tube, which was the seat of the second ectopic gestation, was apparently normal, and which was retained with the hope that the woman would have a child subsequently. He had encountered two other cases of repeated ectopic pregnancy in which the first operation was done by another operator, so that he did not know the condition of the tube at that time. He was perfectly willing to preserve the tube and the possibility of future conception in every patient who desired to have children. On the other hand, if he found the opposite tube was diseased, and especially if a number of these women were fairly well advanced in years, that is thirty-five or forty, and had had their share of children, he thought we should in every way make these patients just as well as we possibly could for the rest of their lives, and save them all future trouble. He could see very little use in leaving behind a uterus which might have been the seat of inflammatory trouble or adhesions about it as the result of operation if it was only going to cause trouble.

In regard to bleeding without pain, all but one of these patients gave a history of uterine bleeding at some time during the illness. In one case the bleeding preceded the pain for three or four weeks, and he could not account for it except probably there was the beginning of the termination of pregnancy in which the bleeding between the gestation sac and the wall of the tube was not sufficient to give rise to any serious symptoms. In regard to preserving the ovaries, in nearly every instance one ovary was preserved.

Operation for the Cure of Rectocele and Restoration of the Function of the Pelvic Floor.—Dr. George Gray Ward, Jr., of New York City, said the operation was especially applicable to cases of large rectocele. The conditions present in a rectocele were the same as in a cystocele. There was a true hernia or prolapsus of the rectum just as in the bladder. Likewise the bowel had been enlarged and pouched by distension, so that there existed an actual increase in size of the gut similar to the condition at the base of the bladder in cystocele. The same principle was applied in this operation to cure the rectocele as was employed in the modern radical operations for the cure of cystocele, the rectum was completely separated from the entire posterior wall of the vagina and was placed higher up in the pelvis. The author described the operation and gave the technique used by him in perineorrhaphy.

The Relation Between the Blood Pressure and the Prognosis in Abdominal Operations.—Dr. George W. Crile of Cleveland, Ohio, stated that the relation between the blood pressure and the prognosis in abdominal operation was based upon two extremes, namely an extremely low blood pressure and an extremely high blood pressure. Providing the heart was normal, they could now control the low pressure phase by transfusion of blood, by mechanical means or by saline infusion. The high blood pressure was far more difficult to control because it was difficult to control the factors that produced this condition. If there was cardiovascular disease due to infection or to lues, nitroglycerin might exert little control, although there was a type of cardiovascular disease that was controlled by nitroglycerin. It was not wise to reduce the blood pressure by bleeding, and aside from nitroglycerin and hygienic measures, there were no other remedies. Therefore, as a matter of fact the high blood pressure was likely to be a mor dangerous factor than was low blood pressure. Whether the blood pressure be abnormally high or abnormaly low the patient was more apt to have complications such as thrombosis, emboli, pneumonia, nephritis, bronchitis, indeed, the abnormal pressure played into the hands of the usual dangers and complications of abdominal operations.

If operation be so performed that the nervous system remained uninjured, the blood pressure unaltered, then the maximum degree of safety would be reached. This he had found could be done on the principle of anoci-aassociation.

Studies in Blood Pressure Before, During and After Operations Under Local and General Anesthesia.—Dr. Joseph C. Bloodgood of Baltimore, Md., said even today, with better anethesia, with better technique, we had a mortality. The mortality was not from simple appendectomy and from other simple operations, but it was from the graver operations, such as resection of the stomach, resection of the colon, the more extensive operation for cancer of the uterus, and the more difficult operation of myoma of the uterus. There was a mortality, and if there was an autopsy on such a patient we would find no infection of the wound, no break in the technique of the intestinal suture, no hemorrhage from the pelvic operation, but still the patient died. Carefully followed, they died as a rule within forty-eight hours or three days with a gradual lowering of blood pressure, with a gradually increasing pulse, with little or no fever, or they died of complications, which in the healthy indivdual were not serious. Patients died from complications of the kidney, and anuria, complications of the heart, complications of the stomach, such as dilatation. There was this mortality in surgery today which had no relation to infection and no relation to faults in technique in the sense of hemorrhage, in the sense of faulty suture of intestine where there would be peritonitis, in the sense of incorrectness which would produce intesinal obstruction, but in the sense of death and shock or death from complications that were due to shock of the operation. These complicataions were chiefly dilatation of the heart, dilatation of the stomach, and faulty kidney function. He was trying to give in a practical way how they were being forced to investigate and to adopt the method of Dr. Crile.

In the last four or five years due to the investigation of

the literature on the subject, and stimulated by Dr. Crile's work in the laboratory and clinic, he had attempted to follow his technique, and he thought the most practical thing he could say to them was to follow his technique in every case. We must remember, however, that to accomplish something that was difficult, something that was more than ordinary, we must practice. From his experience now covering three years, if he wished to develop the technique of anesthesia and operation and to give these handicapped patients with an extraordinary operation the best opportunites for reccovery, we must practice this newer technique in every case until we had gotten it fully developed.

The Diagnostic Value of the Electrocardiograph Before Gynecological and Obstetrical Operations.—Dr. Hugo H. Freund of Detroit, Mich., gave a short description of this instrument and described the various waves. He spoke of the application of the electrocardiograph to hospital cases, especially those in which the patient's cardiac condition was in doubt. He showed lantern slides deonstrating the various forms of cardiac irregularities as recorded with the electrocardiograph. The advantage of this form of graphic work over that of clinical bedside examination and over certain forms of syhpgmographic tracings was discussed. Some stress was laid upon the type of electrocardiogram that called for operative interference in pregnant women.

The Conduct of Gynecological Operations, also of Pregnancy and Labor in Acute and Chronic Affections of the Heart.—Dr. J. Clarence Webster of Chicago said operations should be avoided in active or recent valvular diseases, dilatation or myocardial degeneration, except in conditions of extreme emergency. General anesthesia might greatly increase the risk by causing coughing, straining, vomiting, respiratory embarrassment. Slow administration with free admission of air or oxygen was necessary. Local anesthesia was of importance in such cases. In slight or well compensated affections, regular methods of anesthesia should be employed.

As regards pregnancy, women with heart disease should not become pregnant. If pregnancy occurred it was on the side of safety to advise early abortion, especially if there was recent acute disease of any variety, old or mitral disease or old lesion with failure in compensation.

With reference to labor, if the patient's condition was good, the first stage, as in normal cases, all strain and excitement should be avoided. It was advisable to avoid straining in the secondary stage by artificial delivery, forceps or turning under anesthesia. In the third stage, it was best to separate the placenta annually allowing some lots of blood. A woman at term with failure in compensation or embarrassed circulation probably had the best chance if delivered by vaginal or abdominal Cesarean section.

The Significance of Anemia as an Operative Risk.—Dr. Henry T. Byford of Chicago stated that for surgical purposes we might divide anemia into two groups, namely those with compensation, and those without. The former class were good operative risks, the latter poor ones. He pointed out the characteristics of the former, likewise the characteristics and complications of the latter, and cited illustrative cases.

Treatment of Puerperal Thrombophlebitis.—Dr. Palmer Findley of Omaha, Neb., reported ten cases, reviewed the literature on the subject and said: "With this review of my recent personal experience with puerperal thrombophlebitis, together with the expressions of opinions of many of our workers in the field of obstetrics, I submit the following for consideration: 1. The Trendelenberg operation is surgically correct in theory, but as a practical proposition it is a questionable procedure. 2. The difficulties involved in the making of an accurate diagnonis before opening the abdomen are as yet insurmountable; furthermore, it is not possible to judge with accuracy the extent of the infection within the veins or elsewhere after the abdomen is opened. We cannot rely upon the sense of touch to locate with certainty the limits of a thrombus, nor can we judge with certainty the presence or absence of pus within the veins. Failure to find bacteria in the general circulation gives no absolute assurance of the localized character of the infection, nor can a physical examination of the lungs and other viscera exclude the possible presence of metastatic foci. 3. It is in direct violence to our rules of practice to traumatize tissues in the immediate neighborhood of a virulent infection.

"In reviewing the reports of cases I have been seriously impressed with the boldness with which some operators violate this time-honored principle of surgery. If the infected veins are not dissected out, have we not locked the thief in the stable when we do no more than ligate above the zone of the infection, and if we do dissect out the infected veins do we not incur serious hazards in the way of disseminating the infection? Furthermore, the risk of dislodging a thrombus in exploring the pelvic veins should be reckoned with. 4. It is a physical impossibility to ligate all the veins leading from the genital organs, and unless all channels are blocked there can be no assurance of checkmating the infection. Among the ardent supporters of the operation are those who would ligate the lower end of the vena cava and both spermatic veins, claiming that the collateral circulation can be depended upon to re-establish the return circulation. Is this not an argument in favor of the contention that the venous channels leading from the infected uterus cannot be wholly controlled by ligatures? 5. The physical resistance of all cases of puerperal infection is far below par, a fact which makes us cautious in adding further to their burdens. We might well rob them of the little resistance they possess. 6. Little dependence can be placed upon serum and vaccines in these cases. 7. Whatever may be our views on the question of ligation of veins or upon the administration of serum and vaccines, we are all agreed that the body resistance may be supported by fresh air and nourishing food."

The Calcium Content of the Blood During Pregnancy, Labor, and the Puerperium.—Dr. W. H. Morley of Detroit stated that calcium was a normal constituent of the blood. Its function in promoting clotting of the blood was explained. The determination of the amount of calcium in the blood was usually done by the volumetric or by the gravimetric methods. Either of the two mentioned methods required a large amount of blood in order to lessen the percentage of error. The author described a simple yet accurate method of determining the amount of calcium in the blood. He presented a short report of cases in which this method had been applied, and stated what it had accomplished and what the knowledge of the calcium metabolism might show in physiology and pathology of pregnancy, labor, and the puerperium.

What Are the Best Methods of Educating American Women Concerning Cancer?—Dr. Frederick J. Taussig of St. Louis, Mo., stated it was almost impossible to have printed in a lay periodical intended for general distribution any article upon so distasteful a subject as cancer of the uterus. The only way it could be done was to incorporate it in a general article on cancer and couched in special paragraphs referring to uterine cancer in such words as not to give offense. In spite of the wide circulation thus obtained through some of our women's magazines, he did not specially favor this method as its lack of directness tended to diminish its effectiveness. He suggested an occasional article in the journals of nursing, besides the distribution of special leaflets giving concise information as to early symptoms. Such leaflet had better be given in person by the doctor, the nurse, or the social worker to the laity. Leaflets that supplied the necessary information were more apt to be read if presented personally than they were if sent by mail. Much could also be accomplished, in his opinion, through the agency of womens' clubs in the distribution of literature and pamphlets.

There was a directness in knowledge acquired by word of mouth that ordinarily made it better retained. Hence he believed much could be accomplished by lectures and personal conversation that mere printed matter failed to bring about. The lectures might be given either directly to the laity, before women's clubs, or social settlement organizations, or they might be given before groups of such persons as would be most frequently called upon for advice, such as nurses, midwives, teachers, social workers, ministers or druggists. He recommended that special stress be laid upon the early symptoms of breast and uterine cancer in the curriculum of all nurses' training schools and all colleges of midwifery.

Report of the Committee on Ways and Means in the Matter of Impressing Physicians and Educating the Public in the Necessity of Early Diagnosis and Operation in Cancer.—This committee consisted of Drs. Howard C. Taylor, Frederick J. Taussig, and Leroy Broun, who reported that to accomplish these ends they were convinced that little could be done of lasting value excepting through an organized body, the sole purpose of which would be to conduct the needed campaign of education, of scientific assistance, and collection of data. They further believed that such a society should be of national scope, embracing all interested societies and organizations together with lay people throughout America. The work of this society should be carried on by a competent paid executive secretary and his office corps under the guidance

of a central committee of surgeons to be appointed by its Board of Directors. The need of such an organization and the possible good to be accomplished through its labors were presented to certain public spirited women of New York City. Through their efforts and the hearty co-operation of the members of the American Gynecological Society, together with prominent surgeons and lay people, a meeting was held in New York City. At this meeting the present needs and status of the cancer problem were presented in full before them.

At a later meeting of a committee on organization consisting of lay men appointed by this body the sum of $5,000 was guaranteed towards the expense of such a society for the first year. The committee was authorized not only to make a statement to the American Gynecological Society of this guarantee, but also to present the following resolution:

Resolved, That we request the American Gynecological Society to present the matter to each of the branches of the said congress interested in the subject and ask each of them to appoint a committee of two or more members to cooperate with them in forming a national organization for educational and publicity work with the recognition and treatment of cancer, and that they meet in such committees as soon as possible after the meeting of said Congress of Physicians and Surgeons to be held during the week beginning May 4, 1913.

The committee recommended the endorsement and the enthusiastic cooperation of the society in the formation of such a national body. The committee further recommended that the American Gynecological Society appoint committees of two each to present this resolution to such component societies of the Congress as they might deem interested in this matter, with a request for their co-operation.

The resolution was adopted and the committee was appointed.

Officers.—The following officers were elected for the ensuing year: *President*, Dr. J. Whitridge Williams, Baltimore, Md.; *Vice-Presidents*, Dr. Thomas J. Watkins, Chicago, Ill., and Dr. Howard C. Taylor, New York City; *Secretary*, Dr. Leroy Broun, New York City, re-elected; *Treasurer*, Dr. J. Wesley Bovee, Washington, D. C., re-elected.

Place of meeting, Boston, Mass.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

Thirtieth Annual Meeting, Held in Washington, May 6, 7, and 8, 1913.

The President, Dr. Charles L. Minor of Asheville, N. C., in the Chair.

Tuesday, May 6—First Day.

On the Auscultatory Determination of Early Pathological Changes in the Lungs.—Dr. Henry Sewall of Denver, Col., read this paper, and briefly summed up the evidences that had been presented as follows: (1) Auscultation was capable of giving the earliest objective information of physical changes in the lungs. (2) Such a study demanded analysis of the sound into those vibrations due to resonance of the viscera and those of the chest wall, and that the latter vibrations could be damped by pressure of an appropriate form of stethoscope. (3) Vibrations transmitting the whisper were confined almost wholly to the viscera. (4) The modifications of the voice sounds by which their quality became more amphoric and their duration prolonged into an echo were the striking characters which, when accentuated by stethoscopic pressure, indicated pathological changes in the viscera. (5) The character and distribution of vocal signs over the normal chest were sufficiently constant, so that a topographic study of the chest by auscultation might definitely suggest, through recognition of departures from the normal, the intensity and distribution of morbid changes within the lungs, even when these changes were too slight to appeal to the senses through any other methods.

"Auricular Flutter" with a Report of Three Cases.—Dr. Frank Taylor Fulton of Providence, R. I., said that auricular flutter was a term applied to a condition which was characterized by an extremely rapid action of the auricle, the rate being usually somewhere between 200 and 330 per minute. It was the result of some pathological impulse formation. The ventricular action might be varied. As a rule, there was always some grade of heart block. Most commonly the ventricle rate was one-half that of the auricle; it might, however, be one-fourth that of the auricle, or the transmission of the impulse to the ventricle might be very irregular, so that the pulse might closely resemble the pulse of auricular fibrillation. Flutter was closely related to fibrillation, as well as to regular tachycardias of less rapid rate than itself. The condition had been considered as rare, but the electrocardiograph had demonstrated that it was probably not very uncommon. It might be detected by the use of the polygraph, although the tracings made by this means were sometimes extremely difficult to interpret. It was not necessarily a permanent condition; the heart action might return to normal and remain so for a long time. It sometimes occurred in paroxysms; the case in point was paroxysmal in type and had been under observation for seven years, during which the patient had many attacks, the paroxysms lasting at times for ten or twelve hours or more, but more lately had been less severe and lasted only for an hour or so. Tracings were presented showing the radial and venous pulse during the paroxysm, and at the time of transition to the normal rhythm. The following was a summary of the three cases he reported:

Case I.—A man of forty-eight suffering from progressive, chronic nephritis with paroxysmal dyspnea and considerable edema, suddenly developed an irregular heart action after nearly three months in the hospital. This lasted for a month when the rhythm suddenly became normal. There were no noticeable symptoms with the onset or end of the attack, but the edema was considerably more marked while the irregularity persisted. Cheyne-Stokes breathing was present at the time of the return to the normal rhythm. Digitalis in moderate doses of the tincture was being administered during most of the irregularity, but there was no evidence of its having any effect.

Case II.—A man of fifty-four with gradually increasing dyspnea and edema for a year came under my observation with chronic nephritis and an enlarged heart in a stage of decompensation and a pulse of from 136 to 138 uninfluenced by posture or exercise. The auricular waves were present in the venous tracings at the rate of 272 per minute. With rest in bed the improvement was steady but the pulse was not slowed until after eight doses of digitalis when it became regular, the latter being due to an increased grade of heart block.

Case III.—A retired business man of seventy, with neurotic tendencies, under observation for seven years, had had attacks of palpitation for ten years. These followed a nervous breakdown. The attacks came on at irregular intervals every few weeks and were characterized by a slight sensation of oppression in the precordium, apprehension, tendency to cough, and an irregular pulse of about 100 per minute. There was no marked disturbance of the circulation. The onset and end of the paroxysms were generally definitely recognized unless the end came during sleep. Between attacks there was no evidence of any cardiac or renal insufficiency. The patient thought they usually came on as the result of some emotion or indigestion associated with gas. He had been on small doses of digitalis for about fourteen months. During that time he had had five attacks. Four of these were observed and in two a polygraph tracing was obtained showing the transition from the abnormal to the normal rhythm. The transition was marked by a very long standstill of the heart, in one instance more than five seconds. Twice at the change, the patient had spoken of feeling faint and the sensation of things growing black. The pulse tracing was very irregular but there was occasional evidence of spacing and the C-waves in the venous curve were complicated by A-waves, so that often the former could not be identified. There were occasional runs of auricular waves at the rate of about 330 per minute.

Richie divided the cases of flutter into four groups, this division being based on the symptomatology. First, those in whom there might be or might not be other signs of cardiac disorder but in whom the symptoms could be ascribed to the increased auricular rate and the consequent rapid ventricular action. In these cases the ventricular rate was generally one-half the auricular, though rarely it was the same as the auricular. Such cases might also develop some irregularities. Second, cases with a history of old standing cardiac disease with general edema and dyspnea and in whom flutter developed. With the onset of flutter the condition in these cases usually became worse. Third, cases in which there was a fairly marked degree of heart block as in the case of Hertz and Goodhart, so that the ventricular rate from the onset was slow. Fourth, cases in which flutter might develop where there was complete dissociation of the auricular and ventricular rythym.

Presidential Address. A Retrospect and a Prospect.—Dr. Charles L. Minor of Asheville, N. C., said that a

whole generation had elapsed since the founding of this society and in so progressive a profession as theirs twenty-nine years brought changes so great as to almost revolutionize it, through the opening up of new territories and the development of new ideas. Bacteriology, asepsis, antisepsis, the whole brilliant hypothesis of immunity and its evolution of serum and vaccine therapy, laboratory diagnosis and their knowledge of tuberculosis, marked the steps in their progress. When such changes occurred in so short a time it was evident that only by constant growth and by adaptation to new conditions could medical men and medical societies hope to keep abreast of the times. It seemed to him that he might well devote the time of the Presidential Address, not to the consideration of medical topics, but rather to a review of their past that, from it, they might draw inspiration and suggestions for their future. Few of them had had time to inform themselves of the work that their predecessors had done in this society; if they did they would be surprised at the amount of valuable material that had first seen the light here. The study of tuberculosis had taken a large place in their work and the future historian of the tuberculosis campaign in the United States could not afford to ignore what had been done by the members of this society. But they should not be chiefly a society for the study of tuberculosis; they should take pride in the fact that they had been active and prominent in founding the National Association for the Study and Prevention of Tuberculosis. Again they had a right to feel proud of the admirable work in diseases of the lungs and heart which had been done here, and especially on the physical diagnosis of those diseases. Again their various mineral springs had been carefully studied and much information as to their qualities had been collected, though they were far from having the full information obtainable about the various European hydrotherapeutic resorts and there was a movement in Congress now, for which their support was requested, to have the springs of the United States carefully analyzed. If they desired in the future, as in the past, to hold an honorable place among American medical societies they should critically study present conditions in order to see what they could do to advance their association. They should admit only men whose positions were established and who had a right to apply. They had reached a critical period in the history of this society, and climatology, even with the powerful addition of diseases of the lungs and heart, no longer offered a sufficient field for the activities of the society. They must widen their borders and let it be known that climatology was not the chief center of their interests. They must feel themselves free to study all subjects within the realms of clinical medicine; only so could they hope to keep up with the march of modern medical progress. There was, therefore, a very real demand for a society strictly clinical in its aims and scope and where all men interested in general clinical medicine, of which climatology was only a small part, could bring their problems for discussion. The members of the society must realize that not good fellowship alone, but the ability and willingness to do first class clinical work and to read strong papers would be necessary for entrance into their ranks. Let them call their association the American Climatological and Clinical Association, or possibly better, the American Clinical and Climatological Association. Let them amend their constitution so as to open their meetings to the discussion of all topics of general clinical medicine.

Wednesday, May 7—Second Day.

Election of Officers:—*President*, Dr. James M. Anders of Philadelphia; *First Vice-President*, Dr. Lawrason Brown of Saranac Lake, N. Y.; *Second Vice-President*, Dr. Will Howard Swan of Colorado Springs, Colo.; *Secretaary* and *Treasurer*, Dr. Guy Hinsdale of Hot Springs, Va.

The Effect of Climatic Changes on Rheumatism and Neuritis.—Dr. James Dudley Morgan of Washington, D. C., said that though there had been reference from earliest times to climate and the influences of the same had been variously estimated, there was today still much confusion as to what effect meteorological changes had on certain disorders, and what particular climate was favorable, and what would help some of the more common diseases with which the profession had to contend. Hippocrates spoke of how the body suffered from winds, seasons, climates, and localities, and of the exposure of the Grecian cities to various winds, and of the influences they had. Galen had annotated this work of Hippocrates. Hipparchus had written of climates and divided them as far as they were known into eight, extending from Mercoe to the Nile, to and including the British Islands. The literature in reference to the effects of climate on rheumatism, gout, and neuritis was astonishingly meager, and many hours spent in reference work at the library of Congress and the library of the Surgeon-General, U.S.A., had brought to light little on the subject. Dr. Haviland in 1855 seemed to have been the first to attempt to discover the influence of climate and configuration upon rheumatism. In the present light of the generally accepted etiology of rheumatism, Dr. Morgan's paper did not presume or attempt to show that rheumatism was caused by any other factor than an infection, but tried to draw a correlation between the primary attack and the weather and the tendency of recurring attacks to be often associated with changed conditions of the atmosphere. Many writers had observed that cases of acute rheumatism were not distributed evenly throughout the year, and so humidity had been given much attention (Garrod, Lobert); Longstaff, Newsholm and others considered the relation between humidity and rheumatism to be an inverse one; others that there was no marked coincidence between the cause of rheumatism and rainfall. It was clear that there must be some reasonable basis for this discussion. Rheumatism was a disease of temperate climate, not of arctic regions, and in the temperate climates was not always most common in winter. Neither was it most common at the two extremes of life. In moderately low temperature accompanied by moisture were the times when they found rheumatism more prevalent. Besides moisture and temperature, ventilation seemed to have much to do with the prevention of rheumatism. Too much could not be said of ventilation and a locality that was open and airy. There was a popular idea that rheumatism, neuralgia, and gout were made worse by an approaching storm.

"Hark how the chairs and tables crack,
Old Betty's bones are on the rack!"

In the case of Captain Catlin, which had been referred to by Dr. S. Weir Mitchell, the distance of a storm could often be predicted by the recurrence of neuralgia. Dr. J. M. Rodd had spoken of the strange meteorological phenomena of this country in the way of magnetic storms. These moving somewhat like a cyclonic disturbance across the continent from west to east, had also an effect upon them in some mysterious way, and the patients had neuralgic and rheumatic pains intensified. If the millennium were at hand, or they had the land of Utopia, they would order for the rheumatic patient a combination of dry soil, low humidity, equable temperature, and an airy situation.

The Climate of San Diego, California, Region with Relation to Renal Disease.—Dr. P. M. Carrington, Surgeon, U. S. Public Health Service, read this paper. It had been said that figures did not lie, but that liars sometimes used figures; in considering mortality statistics with reference particularly to the chronic diseases, some corrections or explanations were necessary to make them tell the truth, for in their system of collecting vital statistics no provision was made for charging back to the locality of origin, deaths of transient residents, from diseases contracted elsewhere than at the place of death, so that in the Southwest, for instance, where large numbers of consumptives resorted, the death rate from tuberculosis was high, although the climate of that region was a most favorable one for consumptives. In concluding his paper Dr. Carrington said that experience showed, and opinions of those whose judgment they must respect, supported the proposition that renal diseases were more prevalent in climates subject to great and sudden changes of temperature and where other causative factors were practically the same as in regions where such diseases were less prevalent. Vital statistics, while not so conclusive, in general bore witness to the same facts. The experience and testimony of their confreres in localities of equable climate was to the effect that nephritics did well, felt better, lived longer and even in some cases seemingly recovered in climates of which San Diego presented an example. That a part of the observed beneficial effect might be due to more sane modes of living was admitted, but both reason and experience persuaded them that the even climate must be credited with an influence in the general good results, even though the exact proportion of its influence was not demonstrable.

Clinical Observations on Blood Pressure.—Dr. Judson Daland of Philadelphia, Penna., read this paper. He said that the frequency of errors in the making and interpretation of blood pressure records suggested the desirability of bringing the subject before their association for discussion. The small spring sphygmomanometer was employed by most physicians but the mercury manometer should be preferred because of its greater accuracy. Diastolic pressure observations were often omitted whereby valuable information obtained from a study of the low

and mean pressure was lost. Usually but a single blood pressure record was made, although it was often necessary to observe the effects of work, rest, sleep and emotional excitement. Blood pressure depended upon (1) the amount of resistance offered by the capillaries and arterioles; (2) the elasticity of the arteries; (3) the force of the heart; (4) the amount of blood in the arterial system; and but slight importance was to be attached to the viscosity of the blood. The most important factor, clinically, was the state of the vasomotor system. This system might be considered from the standpoint of the vasomotor center in the medulla, the local vasomotor centers controlling regions of the body, as, for example, the brain or the gastrointestinal tract, and the nervous mechanism controlling individual or groups of capillaries or arterioles. These centric and peripheral centers were readily acted upon by stimuli from various parts of the body, as for example, the cerebral cortex, the skin, regions the seat of intense pain, and also by toxemias, variations in the secretions of the thyroid, the adrenals, or the ovary. Physiologically, blood pressure varied at different times of the day, and was influenced by rest, cerebral or muscular work, and emotional or physical excitement. Variations thus induced were modified by disease. A sudden unexpected noise, such as produced by a china bowl falling to the floor and breaking with a loud crash, had produced a sudden temporary increase of blood pressure of from 20 to 30 mm. Furthermore, it was evident that a correct interpretation of blood pressure records, more especially in those of a nervous temperament, required, not only the selection of a proper instrument and correct technique, but also that the patient be under average ordinary physiological conditions. Multiple blood pressure examinations, under various conditions, were often necessary before sufficient data were secured upon which to base a proper interpretation. Idiosyncrasies regarding blood pressure might be expected analagous to those observed in the pulse rate, the respirations, and the temperature. A man engaged in heavy manual labor, when confined to bed for some weeks from a non-febrile disease, not infrequently showed secondary hypotension, due to prolonged rest, muscular inactivity, and relaxation; whereas such patients, after a day's work, showed a higher blood pressure, which would be still higher while at work. Occupations involving great responsibilities and strain of the nervous system tended to hypertension; and the blood pressure of an orator of a nervous temperament was apt to be high while delivering an oration. Many surgeons showed hypertension owing to the great responsibilities and excitement attending serious operations.

Temperament played an important rôle in the production of variable and high blood pressure, the phlegmatic showing the least and the neurotic the maximum variations. Extraordinary variations, all tending to hypertension, were observed in the neuropathic. Driving an automobile for two hours through the crowded streets caused an increase of 30 mm. in the systolic blood pressure and 15 mm. in the diastolic; whereas under similar conditions, while driving quietly where there was but little traffic, caused an increase of but 10 mm. in the systolic and a decrease of 5 mm. in the diastolic pressure. These variations might be interpreted as resulting from excitement produced by automobiling. A neurotic woman stated that the act of taking the blood pressure always caused fright similar to that occasioned by the near approach of a rapidly moving horse and carriage, while crossing the street. Fright, thus induced, caused a systolic pressure of from 205 to 235 mm. and a pulse pressure of from 65 to 90 mm. Physiological conditions must be secured before making a blood pressure determination. No patient, more especially one of a nervous temperament, should be examined immediately after arriving at the physician's office, unless a control observation was made later, and any evidence of haste or excitement should be avoided. The first observation was made in the sitting posture, the second after reclining for a few minutes, and a third immediately after making ten vigorous bending movements, touching the fingers to the floor with each movement. The average systolic pressure in an adult in the sitting posture, under average physiological conditions, was from 120 to 130 mm., and the average diastolic pressure was 20 or 30 mm. less. Occasionally the normal blood pressure of certain individuals might be 5, 10, or more mm. higher or lower. In recumbency, as a rule, the systolic and diastolic pressure fell 5 or 10 mm., although occasionally the systolic pressure might remain unchanged and the diastolic pressure fell 5 or 10 mm. Immediately after exercise the systolic and diastolic pressure were ordinarily 5 or 10 mm. higher than that obtained in the sitting posture. The average pulse amplitude or pulse pressure was about 20 or 30 mm. Occasionally it was desirable that the blood pressure be determined after rapidly walking a certain known distance, or after running rapidly up and down three flights of stairs. Valuable information as to the state of the nervous system, and especially of the vasomotor system, was obtained from blood pressure observations based upon the foregoing considerations. In many cases of failure of compensation of the heart the blood pressure tended to decrease and the pulse pressure remained approximately normal. In well marked aortic regurgitation, where compensation was preserved, the systolic pressure was usually high, the diastolic low, and the pulse pressure might be as much as 60 mm. or more. When the myocardium was organically or functionally weak, there was a tendency to hypotension. When compensation had been restored in the various diseases of the heart, the blood pressure might not be materially altered. As blood pressure was dependent, not alone upon the condition of the myocardium and vessels, but also upon the caliber of the artieroles and capillaries, extreme variations in blood pressure might be observed in the course of various forms of heart disease.

Uremia was a cause of persistent hypertension and asystolic pressure of 180 mm. to 315 mm. had been observed. Hypertension from this cause was usually uninfluenced by most drugs. A reduction of 20 mm. or more might be secured after profuse sweating induced by a cabinet bath or pilocarpin. In his experience nitroclycerin had been disappointing in its effects upon most cases of hypertension, even when given in ascending doses at short intervals, and usually the reduction in pressure had been slight and transitory, with no symptomatic improvement. Hypertension in uremia might be chiefly due to stimulation of the centric or peripheral vasomotor centers. When the nervous and muscular mechanism of the heart was normal, an increase in the strength of each systole might be largely due to an increase in the intraventricular pressure secondary to vasomotor constriction. Vasomotor instability was a frequent cause of blood pressure variations. In certain cases of acute lead poisoning, gout, intestinal toxemia and disturbance of the chemistry of intestinal digestion, hypertension had been observed.

By far the largest number of cases of hypertension in private practice occurred in nervous exhaustion, particularly in those who were neurotic or neuropathic. Comparatively insignificant causes were capable of producing in these individuals notable variations in blood pressure, usually tending toward hypertension. In psychoneurasthenia, readings of from 170 to 315 mm., with a pulse pressure of from 30 to 60 mm. or more had been observed. In chronic nervous exhaustion hypertension might persist continuously for months or years, eventually causing arteriosclerosis and left ventricular hypertrophy which might eventually lead to mitral and cardiac insufficiency. In certain cases of nervous exhaustion with hypertension, variations of 10, 15, or 20 mm. might occur within a few minutes, apparently due to vasomotor ataxia. In certain neurasthenics the blood pressure in the sitting position was unchanged by recumbency; or the systolic pressure might rise, and the diastolic pressure might increase or decrease. In like manner, exercise might produce no change in the blood pressure as compared with that taken in the sitting posture and occasionally a lowering is observed. These marked variations from the normal seemed best explained by viewing the vasomotor system as incoordinate or ataxic. Vasomotor ataxia presented its most classical clinical picture in certain cases of well marked menopause, many of them presenting not only extreme variations, but at times extreme hypertension rising to 200, 235, or even 270 mm., associated with a pulse pressure varying between 60 and 110 mm.

Hypertension might be caused by excessive secretion of the thyroid or adrenals. In a case of advanced Addison's disease, with great destruction of the adrenals the systolic pressure was 90 mm. and the diastolic pressure was 70 mm.

An Inquiry into the Cause of Bronchial Asthma.—Dr. Robert H. Babcock of Chicago presented this paper. He said that in order to facilitate the discussion of the etiology of bronchial asthma, the disease might be divided into two clinical forms. In one, the paroxysms of dyspnea first made their appearance in early childhood and thenceforth occurred with varying degrees of periodicity. They were induced by some irritant which the sufferer knew would excite his asthma. The paroxysms lasted a variable length of time and usually were arrested by some particular remedy. During the asthma-free intervals the patient was free from dyspnea and might feel entirely well. The individual might be permanently relieved of his asthma by change of climate, especially when the exciting

agent was found to be the pollen of some particular plant, although in some cases mere change of climate or locality proved remedial even when no special irritant could be identified. The practical application of what Dr. Babcock presented was this: In every case of asthma search for some form of chronic infection of the nasal accessory sinuses, in a chronic hyperplastic ethmoiditis, or in some closed cavity in any other part of the body and finding it advise its removal by surgical interference. If the absorption of a foreign protein could be prevented in this manner, it was likely that the asthmatic seizures would be prevented or greatly ameliorated. Of course in cases of asthma traceable to animal or vegetable emanations, or to some article of food to which the person had become sensitized, they could do no more than advise the avoidance of exposure to the exciting cause. Nevertheless, the understanding of the etiology of this distressing malady certainly gave them a basis for rational and effective therapeutics in many instances that otherwise might go unrelieved.

What Relation, if Any, Have the Tonsils to Pulmonary Tuberculosis?—Dr. E. Fletcher Ingals of Chicago read this paper. He said that during the last fifteen years many articles had appeared in medical journals on the relation of the tonsils to pulmonary tuberculosis. At the early part of this period it was frequently claimed that the tonsils were a common portal of infection for the pulmonary disease, but subsequent research demonstrated that the tubercle bacilli might penetrate the tonsils and pass through them to the lymphatic cervical glands, causing tuberculosis of the latter, without any involvement of the faucial tonsils. It was shown, however, that there was no connection between the cervical glands and the pulmonary lymphatics. In a small percentage of cases the tonsils appeared to be primarily involved in cases of pulmonary tuberculosis, but usually tubercular changes in these glands were secondary and the bacilli appeared to have been absorbed from the sputum. It had been shown that the tonsils were the portal of entrance for the tubercle bacilli in many cases of tubercular cervical adenitis, yet inflammation of the cervical glands, non-tubercular in character, appeared to be much more frequently due to absorption of infection through the tonsils. The consensus of opinion now was that pulmonary tuberculosis was generally a systemic infection of aërogenous origin, and that when the tubercle bacilli were taken up by the lymphatics they were poured into the general circulation. In pulmonary tuberculosis the bronchial glands might be primarily involved, but this did not appear to be the usual course of the disease. In a recent statement one of the best-known pathologists said that he did not think there was any relation between diseases of the tonsils and pulmonary tuberculosis.

The Nutritional Effect of Intermittent Albuminuria of Adolescence.—Dr. Fremont-Smith of Washington, D. C., reported the cases of two lads, one of seventeen and the other of twenty-one years, who had transitory albuminuria. Both had been under observation for ten years. The elder had entirely recovered. From the opinions of certain authors mentioned, as well as from his personal experience, not only with the two cases detailed, but in many others which he had been able to follow for a less period of time, one was led to the conclusion that transitory albuminuria, intermittent or remittent in character, had little or no effect upon the nutrition of the child. They met with many children who suffered from varied forms of malnutrition in whom albuminuria was never present; in proportion a much larger number indicated malnutrition without albumin than with it. It must of course be accepted that transitory albuminuria continuing for years, though in adolescence, whether primary or succeeding some mild exanthem, required careful care, and in no individual case should one assume that the ultimate result might not be permanent injury to renal structures, but it was significant of the comparative, or complete harmlessness of the condition discussed, that as one followed literature from the earliest imperfect studies to the latest complete analyses, opinion had crystallized in the minds of authors and students of children, that they were dealing with, in most instances, a harmless and passing phase of adolescent life.

Thursday, May 8—Third Day.

The Fruits of Laboratory Work in Relation to Clinical Tuberculosis.—Dr. Edward R. Baldwin of Saranac Lake, N. Y., read this paper. He said the habit of making distinctions between clinicians and laboratory workers had grown up in later times. It was inevitable when the increasing complexity of medical science made a subdivision of labor imperative. The result had been unfortunate in some respects. Inability of the pure clinician to appreciate the laboratory specialist, and on the other hand a contempt for the art of medicine, at least the empirical side of it, on the part of the laboratory man had ensued. When they asked what fruits had come from laboratory work in tuberculosis, one naturally harked back to Koch's discovery of the bacillus, but really one should go still further back. Villemin, in 1865, properly began to bear fruit, and since Koch they had never ceased to improve their diagnosis and treatment with the aid of laboratory studies. It was true much time had been given to it, but so it was with the physician at the bedside. False deductions in the laboratory as well as at the bedside had cost many lives. This was why medicine blundered along toward an exact science but never reached it. Probably no single fruit ever equaled the discovery of the bacillus in importance, and a close second was tuberculin, the value of which was now being appreciated. As an addition to treatment tuberculin had not been such a boon, but in revealing the enormous number of infected individuals, both human and bovine, the whole program of tuberculosis prevention was influenced. The ideas of inheritance were so dominant in the past, it was painful to think what would have happened but for Koch's work. Dr. Baldwin then considered what the laboratory had done directly or indirectly for the diagnosis of tuberculosis in addition to the discovery of the bacillus.

A Year's Observation on Symptoms in Cases of Advanced Tuberculosis in the Los Angeles County Hospital, in Connection with Weather Conditions.—Dr. Charles C. Browning of Los Angeles, Cal., read this paper and presented several charts. In 1908 he reported to the society some observations made regarding the apparent influence on temperature and hemorrhage in tuberculous patients with reference to certain meteorological phenomena. It appeared from that report that unreasonable, or very sudden, changes in temperature appeared to influence the temperature of patients while equal or greater changes occurring slowly did not. Of the cases of hemorrhages reported at that time, it appeared that hemorrhages tended to occur in groups, and of these about four times the number occurred when there was a barometric pressure change exceeding .3 of an inch within twenty-four hours than when the barometric change was less. The hemorrhages appeared to be more frequent if there had been a decided change in one direction, as a marked rise followed by a marked change in the opposite direction, a sudden fall. In his paper he said he wished especially to call attention to some observations extending over a year on tuberculous patients, to present charts which showed the scope of the work, and also to refer to the different phenomena. There were recorded during the year 21,968 patient day observations, with an average of 61 patients charted daily. There was an average of about 70 patients in the wards, but there were a number who for various reasons were not noted. Hemorrhage and death groups were quite noticeable during some months, but not during others. There were recorded 217 hemorrhages, six of which were fatal, and 227 deaths. Climatic conditions could only act to a certain extent as determining factors in producing the symptoms recorded. The conditions which appeared to influence groups of hemorrhages and deaths appeared to be barometric pressure, humidity and cloudiness, each in its turn appearing to be the most prominent index to weather conditions, which seemed to exert a limited determining influence, as shown by the charts presented.

The Influence of Smoke on Acute and Chronic Lung Infections.—Dr. Wm. Charles White and Paul Shuey of Pittsburgh, presented this paper. The mortality statistics were based on reports received through the courtesy of Dr. C. L. Wilbur, Chief of the Division of Vital Statistics of the United States Census Bureau, and also through the courtesy of the various Boards of Health of the different cities. They stated that smoke as a problem of cities' health had its main influence upon the respiratory passages. As types of acute and chronic lung infections, on which smoke might have a varying influence, pneumonia and tuberculosis had been chosen. These diseases had been studied from a statistical standpoint for various cities scattered throughout the United States, and comparisons made with the city of Pittsburgh, which probably had the greatest number of smoky days in the year. In considering the influence of smoke on acute and chronic fatal lung infections, the question of age of distribution, age of city, poverty on the basis of congestion, and topography of the city had been taken into account. The later feature in such a city as Pittsburgh, with high hills and river valleys, allowed a partial segregation of the city into areas of varying smoke density. In other cities, such as Indianapolis, the flat contour did not allow such divisions. The chief

tendency of the study seemed to indicate that smoke had rather a severe influence on pneumonia, with a much less influence on tuberculosis.

The Rôle of Physical Exercise in the Open Air in the Prophylaxis of Tuberculosis.—Dr. James M. Anders of Philadelphia, Pa., read this paper. He said the disposition on the part of physicians was to overlook the importance of muscular exercise in the prophylactic treatment of pulmonary tuberculosis, since the general acceptance of the principle of rest in the treatment of all cases of this disease in which fever was present. The object of this paper was not to attempt to underrate the great value of rest in the active stages of this disease, but rather to emphasize the first-rate importance of systematic muscular exercise as a means of minimizing the number of susceptible persons. The American race, as a whole, was undergoing muscular deterioration. On the other hand, the endurance or resistance of an individual was in direct relation to his muscular development. Muscular development was considered in relation to climate. The prevention of tuberculosis involved something more than physical exercise, but the commanding position of this measure was undoubted. Effect of systematic physical exercise, combined with deep breathing, upon the vital power and resistance of the lung texture was considered. Competitive athletics were not to be encouraged among the young. Increased respiratory exchange in muscular activity increased the nutrition and general health of the body. The details connected with the question of the regulation of muscular exercise must vary with the individual.

The Two Most Important Factors in the Treatment of Tuberculosis.—Dr. DeLancey Rochester of Buffalo, N. Y., read this paper and stated that the mortality from tuberculosis to a considerable degree had diminished in those localities where a vigorous anti-tuberculosis campaign had been waged and this showed that more cases had been recognized in a curable state and by proper methods of treatment had been cured. So far as he knew there had been in the past and there were now no reliable statistics showing the incidence of the disease, so they did not know whether there had been lessening in the morbidity from the disease or not. Personally he believed there had not been. For the prevention of any infectious disease it was necessary to so act upon the tissues of the body as to render them unsuitable media for the growth of the particular microorganism which caused the disease, or to prevent the dissemination of this particular microorganism. Examples of what could be accomplished in the former way were the vaccination to prevent smallpox and the antityphoid inoculation to prevent typhoid fever. Examples of the latter were the prevention of the spread of malaria and yellow fever by the destruction of the particular species of mosquitos which carried the germs of the disease. The preparation of the tissues of the body so that they would not be good media for the growth of the tubercle bacillus had been the aim of the profession for many generations. Merely to mention this fact was sufficient evidence to show what an utter failure had been made. Instruction in regard to destruction of sputum and feces, in regard to precaution as to personal contact with others, and in regard to apartments lately occupied by the tuberculous, were all of value in checking the spread of the disease; but it was Dr. Rochester's opinion that some plan, as outlined, of compulsory reporting of cases and compulsory removal of suitable patients in their proper sanatoria would be much more efficacious than all the other procedures in ridding them of the great white plague.

Cancer Among Native Africans.—E. Legrain refers to the extraordinary rarity among the natives of Africa of malignant tumors, particularly of the internal organs. Isolated cutaneous sarcomata appear to be the main form of cancer attacking these people. Benign tumors are fairly common. Europeans resident in Africa show the same incidence of cancer as the inhabitants of Europe.—*Revue Suisse de Médecine.*

Infantile Lithiasis.—Von Bókay notes that the incidence of this condition varies in different countries. In some parts of the world it is practically unknown. In Hungary and in the central part of Russia along the Volga it is quite common. An analysis of 1,836 cases shows that the disease occurs in children most frequently between the second and seventh years. There were 1,310 cases of vesical calculus, 9 of renal calculus, and 508 of ureteral calculus. In the etiology of infantile lithiasis obstruction to the urinary outflow plays a predominant rôle. The main obstruction is congenital phimosis and the adhesion of the prepuce to the glans.—*Zeitschrift für Kinderheilkunde.*

Therapeutic Hints.

Treatment of Seborrhea of the Scalp.—Sabouraud recommends massage of the scalp every evening with the following ointment:

℞ Resorcin,
Ichthyol,
Yellow oxide of mercury,
Precipitated sulphur, āā 1 gram.
Pyrogallic acid, 0.50 to 1 gram.
Oil of cade,
Lanolin,
Vaseline, āā 10 grams.

The scalp should be shampooed the next morning.—*Journal de Médecine de Paris,* April, 1913.

Thallium Acetate in the Treatment of Hypertrichosis of the Upper Lip.—A. F. Plicque states that this condition which is particularly distressing when present in women is best combated by means of the local application of thallium acetate, as recommended by Sabouraud, in the following formula:

℞ Thallium acetate, 0.30 gram.
Zinc oxide, 2 grams.
Vaseline, 20 grams.
Lanolin, 5 grams.
Rose water, 5 grams.

The action of this ointment is mild and slow, but it is continuous and progressive. It reduces the length and thickness of the down and decolorizes it. There are no bad effects.

The Treatment of Eczema of the Scalp in Infants.—Max Joseph finds that eczema of the scalp in infants responds quickly to the cinnabar salve recommended by Lassar. The formula of this is as follows:

℞ Red sulphide of mercury, 1 gram.
Sublimed sulphur, 24 grams.
Oil of bergamot, 25 drops.
Vaseline, q.s. ad 100 grams.

This ointment is applied to the scalp twice daily on gauze retained by a bandage, and every other day the scalp is cleansed with oil. As soon as the eczema has been transformed into a dry variety the salve is applied only for the night. When the eruption is represented only by a few superficial scales, the following ointment is effective:

℞ Salicylic acid, 1 gram.
Tincture of benzoin, 3 grams.
Vaseline, q.s. ad 50 grams.

Foot Powders for Hyperidrosis.—C. Sabatié recommends the following:

℞ Salicylic acid, 1 gram.
Rice powder, 10 grams.
Talc, 40 grams.

℞ Subnitrate of bismuth, 50 grams.
Sodium salicylate, 10 grams.

℞ Talc.
Subnitrate of bismuth, āā, 40 grams.
Pulverized alum, 10 grams.
Potassium permanganate, 2 grams.

Treatment of Migraine.—Gordon Holmes has employed the following prescription with the most gratifying results in checking the attacks of migraine:

℞ Sodii bromidi, grs. xii.
Antipyrini, grs. vii.
Tinct. cimicifugæ, ♏ xx.
Aquæ, q. s. ad ℥ ss.

This dose should be administered twice a day.—*The Practitioner,* June, 1913.

THE PROBLEM OF THE SOCIAL EVIL CONSIDERED IN ITS SOCIAL AND MEDICAL ASPECTS AND IN ITS RELATION TO THE PROBLEM OF RACE BETTERMENT.*

By J. EWING MEARS, M.D., LL.D.,
PHILADELPHIA.

The prostitute is a product of civilization. As such, she does not exist in barbaric life. No highly civilized people has ever been free from her presence and from the baneful influences exerted by her. Closely interwoven into the meshes of civilization, she has traveled over the pages of history from the days of Moses, the great lawgiver, to the present time. In the varied phases of her life she has sat upon thrones, the consort of potentates; she has taken part in the council of nations, as the mistress of statesmen and councillors; she has exerted her influence and power in the edicts of courts of justice, and as well in the courts of diplomacy and arbitration in which the great questions between the nations of the world have received adjudication; she has accompanied the great armies of the world to the battlefields and has sailed over the seas in the battleships of nations, leading them, as history has recorded, with the song of the siren, to their destruction. Choosing, in the great majority of cases, her mode of life to escape toil as a means of livelihood, insubordinate to discipline and self-control, she is essentially a creature of ease and of luxury, and thrives under conditions of prosperity. She shares with the millionaire his accumulated wealth and deserts him when disaster overtakes him, for which she may have been largely responsible. In some instances, but rarely, she has garnered the profits of her life and has retired upon a competency which has enabled her to lead a life of quasi-reformation and quasi-respectability.

There is another class of prostitutes who are either born into the life of prostitution or who come from the lower classes of the people. In early life deprived of instruction in morality, and of the influences exerted by an environment of Christian living and example, they, from the beginning, become the associates of criminals and partners in their nefarious practices. The life of crime and debauchery they lead soon makes them the subject of specific disease, the victim of the alcohol and drug habits, and they end their days in prison or in the almshouse, entombed on death in a pauper's grave, or mayhap their bodies are delivered to the anatomical laboratory of a medical institution, to be used in promoting medical science, and through the instruction thus given return some good for the great evil their lives have wrought.

I have chosen to bring this subject before you on this occasion, since its discussion is engaging the earnest attention of the authorities of the great cities of our country, and it has as well claimed legislative interference on the part of our government. Our profession is called upon to take an important part in the efforts to solve the problem which it presents in its intimate relation to the problem of race betterment. The social and moral questions which it involves claim the study of the sociologist and philanthropist, arouse interest and stimulate effort in the solution of the great problem which has remained unsolved from the earliest times. The Church, with the moral law in one hand and the flaming sword of punishment in the other, has failed in fruitless crusades to solve the problem. It comes to us to-day, therefore, unchanged in its essential features, adapting itself simply to the conditions which characterize our civilization. These conditions are such, that base as were the sexual orgies which accompanied religious worship among the ancient nations of the East, and those also which gave a name to the cities of Sodom and Gomorrah which time can never efface, the practices of debauchery in the modern cities of Paris and Amsterdam, as well as in the great cities of our own country, cause them to pale into insignificance.

It has been truly said that a problem is not solved until it is correctly solved. Hence the great importance of the careful study of the history of prostitution as it has existed from its very beginning in the world to the present day, in order that those who undertake the solution of the problem may know what efforts have been made in this direction and with what results.

It is futile to attempt to accomplish its eradication from the social life of to-day by the employment of even the hardest methods of punishment which are recorded in Biblical literature. It has survived these methods and comes to us a more difficult problem by reason of the reaction which followed these conditions. The Mosaic code of morality tolerated prostitution so long as it did not touch the race or religion. Even this degree of disapproval was not strictly maintained, as there was at least one prominent person who was the son of a harlot.* Jewish fathers were forbidden to turn their daughters into prostitutes, and the daughters of priests who became prostitutes were punished by burning. There is undoubted evidence that prostitution prevailed extensively in Palestine in the earlier days. Forbidden to reside in Jerusalem and to enter places of worship, they infested the waysides and were known by a distinctive dress. It is asserted that Moses in his ordinances, promulgated concerning the conservation of the public

*Paper read before the Georgia Medical Association at its annual meeting held in Savannah, April 18, 1913.

*Jephthah; Judges xi, 1.

health, gave unmistakable evidences of the recognition of syphilis and of its contagious character (Lev. 45).

In the early days of Greek history there appears, under the edicts of Solon, the first attempts made with regard to the regulation of prostitution and to the establishment of houses for prostitutes which were a monopoly of the State. Stringent municipal regulations controlled the inmates of these houses, relating to a distinctive dress, exclusion from the parts of the town occupied by the better class (segregation), and inhibition from taking any part in religious rites. Here is found the first introduction of police control of the prostitute, and with it the beginning of the difficulties which are encountered by modern administrations.

In Greece there were grades of prostitutes, the superior class consisting of gifted and brilliant members who wielded great power and influence, to such degree as to triumph over the law, opening the door to general laxity in morals and indulgence in sexual excesses and practices of the most debased character.

Among the Romans prostitution was more severely regulated than by any other ancient race. The system of police registration in the early days of the republic was introduced and it has continued until this time as an essential feature of Continental administration. On registration, licenses were issued to prostitutes on payment of a tax. Once placed on the register their names could never be erased and thus they remained forever under an indelible stain. Notwithstanding the enforcement of these measures, which in the later days of the Republic were increased in severity, they failed to stem the rising tide of immorality, the effect being rather to promote its general prevalence, so that the profligacy of Imperial Rome has never been surpassed for gross and obscene sensuality.

Under the influence of Christianity a more charitable attitude was adopted toward prostitutes, social and legal outcasts as they were. In the fourth century the State tax was removed in part and registration was abolished. The effort of Theodora, the wife of the Roman Emperor Justinian the Great (483 to 565), herself a notorious prostitute before her marriage, to establish on the Bosphorus a rescue home for her fallen sisters, was an evidence of a turning point in the treatment of a class which had hitherto been deprived of kindly regard or public sympathy. Its failure, by reason of the hostility of the prostitutes to restraint, was also an evidence of the great difficulty which presents itself in this day in promoting reclamation.

While the early Christian Church laid great stress upon chastity, it was not severe upon prostitutes. Some of the fathers especially recognized their trade as a necessary evil, among them St. Augustine, who felt that its suppression would give rise to and stimulate more destructive conditions of immorality. Vice held possession of the institutions and ministers of the Church before the Middle Ages. This condition was followed by a period of reform, and under a wave of Christian fervor supplemented by a rise of chivalry, a vigorous campaign was made against the prevailing evil. Rescue missions were organized and convents founded for the reception of penitents. Edicts of the Church pronounced it a praiseworthy act to marry a prostitute. The clergy and laity who drew profit from prostitution were banished. In spite of these efforts prostitution flourished everywhere in the Middle Ages, not only tolerated but licensed and regulated by law. In London, in 1161, houses of prostitution were licensed by the bishops of the Church (Winchester) and sanctioned by Parliament—the regulations controlling them were protective rather than repressive. In 1383 the bordels of London were farmed out by the Lord Mayor. In 1546 they were abolished by Henry VIII.

In London the earliest known regulations against the spread of venereal disease were promulgated, the Act of 1161 forbidding the keepers of bordels to have women suffering from the perilous "infirmity of burning" (gonorrhea, without doubt), and to admit men suffering from an "infirmitas nefanda" (possibly syphilis). Keepers violating these regulations were imprisoned and banished from the city. During this period of time the same conditions prevailed on the Continent, prostitution being both protected and regulated, and in many cases constituting a source of public revenue. In France public brothels were established on a large scale. At Toulouse the profits were shared between the city and the University—in some places the trade was a municipal monopoly and farmed out to individuals. The first introduction of medical examination of the inmates of brothels, so far as recorded, occurred in Avignon during the time it was the Papal residence—procuration in later times was punished with extreme severity. In some parts of France prostitutes paid a tax to seigneurs (lords and members of the nobility).

In Germany during the Middle Ages brothels (frauen-häuser) existed in many places—in some built by the towns and farmed out. Admission to these houses was forbidden to married men, the clergy, and to Jews. On Sundays and saints' days they were closed. Hospitality to important guests included placing the public "frauen-häusen" at their disposal. It is recorded that Emperor Sigismund was treated so much to his satisfaction in these houses that he publicly complimented his hosts in cities he visited.

In Italy and Spain the system appears to have been the same. Prostitutes were compelled in different places to submit to local regulations, such as those which required them to wear a distinctive dress, to leave a neighborhood on complaint of other residents, and they were forbidden to frequent wine-shops. At Naples a court of prostitution was established having jurisdiction over all matters connected with prostitution; it led to great abuses, was reformed, and finally abolished about 1689.

At the end of the Middle Ages two causes, (1) fear of disease, and (2) the Reformation, effected a great change. Although the "slighter and graver forms of venereal disease were known to exist in very remote times they attracted very little attention until the fifteenth century. The constitutional character of syphilis was certainly not understood, but it is difficult to understand why more notice was not taken of it by medical, moral, and historical writers in classical and mediæval times; it can only be concluded that it was less widely spread and less virulent than it afterward became; it was thought to have originated *de novo* or to have been imported by Columbus from the West Indies."

The reformation which followed this widespread occurrence of syphilis initiated a general and active campaign against licensed prostitution. On the Continent and in London public brothels were closed and abolished, and prostitutes in Paris were ordered to leave the city in twenty-four hours.

Municipal brothels were never tolerated again. Following these measures of repression the crime of infanticide appeared, with the establishment of foundling-hospitals and an increased prevalence of syphilis. Prostitution was not abolished by these conditions or its prevalence abated.

In 1635 sèvere measures of repression were enforced in Paris. Men who were connected with the traffic were condemned to the galleys for life. Women and girls were whipped, shaved, and banished for life. In England, fornication was punishable by three months' imprisonment, with bail for good behavior. Bawds were whipped, pilloried, branded, and imprisoned for three years; the second offense was punished by death. In Hamburg, brothels were pulled down and the women expelled from the town. A greater reaction followed these measures.

Following these conditions there came in the eighteenth century the establishment of an organized police force for the control of prostitution, with registration of prostitutes and medical examinations at stated times, with the object of the protection of health. To the barber, who was the surgeon at that time, the duty of medical examinations was entrusted. The closure of the public brothels greatly increased the growth of private institutions and nullified the efforts to enforce medical examinations—registration also failed in placing on the registers a full list of those engaged in the traffic. In Germany and in France prostitution was not permitted by ordinances, "but simply tolerated as a necessary evil to avoid greater disorders which are not to be restrained by law or authority, and which take their rise from an inextinguishable natural appetite."

At the present time in France, Germany, Austria, and on the Continent generally prostitution is not forbidden. In the former countries it is regulated by police control, including registration, medical examinations, and confinement in hospital until acute conditions of venereal diseases are passed. Severe penalties are attached to certain violations of the laws—procuration by parents, guardians, and others is punished by imprisonment from one to five years.

In Great Britain the law which dates from the middle of the eighteenth century regards prostitution solely as a public nuisance. Penalties are enforced against violation of the law, including fines, imprisonment from five years to a life sentence—these severe penalties relate especially to the procuration of young girls and enticing them to become the inmates of brothels. The police were required to proceed against common prostitutes for riotous behavior, loitering on the streets, soliciting passengers or inhabitants.

In 1864, a Contagious Disease Prevention Act was passed providing for the compulsory medical examination of prostitutes and detention in hospital of those found diseased in certain garrison towns. In 1866 an important memorial was drawn up by the Royal College of Physicians and Surgeons in favor of the original and amended Acts and their application to a large number of places. A popular agitation, based on moral and humanitarian grounds, was continuously carried on against the Acts, which finally led, in 1866, to their repeal, notwithstanding there was direct evidence strongly in favor of them and the results which flowed from their enforcement. These results were manifest in the diminution of venereal diseases among the troops in the protected towns, the absence of complaints, and the good effect on public order to which clergymen and other residents testified. In India, among the troops of the English Army, an enormous increase of syphilis followed the repeal of the laws requiring compulsory medical examinations of prostitutes near cantonments, and power was given to enforce the attendance at the dispensary of all persons suffering from a contagious disease; brothels were removed and residence of prostitutes near cantonments was forbidden. In the city of St. Louis in our country, from 1870 to 1873, a modified sanitary control of prostitution was attempted, and was most beneficial in its result so long as it lasted.

A letter received from a distinguished physician of St. Louis contains the following information with regard to the working of this system of control. "Under the law every prostitute was registered and examined twice a week and two dollars was charged for the service. With the proceeds the Women's Hospital was built. The law worked well, and under its execution venereal disease was markedly reduced. After two or more years' trial of the system it was repealed, on account of the protest of several ministers that the city was licnsing crime. Thus a good law was repealed and disease ran riot again.

"Venereal disease is more prevalent in this country and in England than in any civilized country of the world, and all because those in authority are influenced by a false sentiment which dominates our social life.

"There are some people who look at the conditions which exist in the world through a vertical crack of study and observation, and naturally their view of these conditions is limited, and bereft of full and proper understanding they see little that gives knowledge and understanding."

The above summary of existing laws and regulations sufficiently indicate the present methods of dealing with prostitution. The French system of recognized houses, with registration and police supervision, is generally adopted on the Continent, while in Great Britain and the British self-governing colonies, and in the United States, comparative freedom exists, without a moral police or one possessing arbitrary executive power independent of the courts of justice.

Experience has proved that all of the systems have their defects and all fail to fulfil their purpose in great cities. On the Continent public order and propriety are preserved, but at the cost of submitting to an arbitrary police rule intolerable to a free people. In Italy there appears to be less prostitution, both actual and visible, than in other countries. An energetic police, under the system in force in Great Britain, is able to keep the streets in provincial towns orderly, but in London the mass of prostitution is so great that the police are unable to cope with it. Important thoroughfares and centres are frequented by large numbers of prostitutes in broad daylight and choked by them at night. Solicitation in the most offensive and flagrant manner is permitted by the police, who seem to content themselves with preventing positive tumults, with frequent failures in accomplishing this. Public brothels, except in Dublin, do not exists to any extent; there they are confined to one street, and there is little or no restraint imposed upon their traffic.

The impotence of the law in preventing the existence of brothels and in securing complete registra-

tion of prostitutes is very evident. The latter, if rigorously enforced, develops clandestine prostitution, and as a result venereal diseases prevail extensively in all large continental towns. Norway, as an exception to other continental countries, keeps accurate records of the prevalence of venereal disease. As a rule the only exact figures available are the military returns furnished by officers of troops in garrison towns.

Tables giving the proportion of admission to hospital from all forms of venereal disease, prepared from 1876 to 1895, show that the percentage of admissions from the British forces is enormously higher than that of the continental forces, where the system of protection is carried out so thoroughly. It is interesting to note that this high percentage was markedly lowered among the British troops during the period of time when the Contagious Disease Prevention Act was in force. Just before this Act came into operation the proportional figure was 260; ten years later it had fallen to 126; protection being removed by repeal of the Act, it rose to 276. In the Indian troops the absence of protection permitted a startling increase, the hospital admissions for primary syphilis rising from 75.5 to 174.1 per 1000, and those from secondary syphilis from 29.4 to 84.9. These statistics would seem to show beyond any question that rigidly enforced registration and medical examination fulfil to a considerable extent the purpose of protecting health.

In 1900 the Prussian government made an attempt, with the coöperation of the medical corporations, to ascertain the amount of venereal diseases prevalent in the kingdom. In reply to circular questions addressed to all members of the medical profession, requesting them to report the number of patients suffering from those diseases in their practice at a certain date, 63 per cent. reported an aggregate number of 40,902 patients. From this information it is estimated that the number of persons attacked at that time in the course of a year was at very least 500,000 in that country alone.

The author (*Encyclopedia Britannica*, 10th edition, A. Shadwell, M.D.) from whose article I have taken the foregoing summary of the history of prostitution, presents his conclusions, drawn from a careful study of the subject, in the following manner: "Prostitution appears to be inseparable from human society in large communities. In different countries and ages it has in turn been patronized and prohibited, ignored and recognized, tolerated and condemned, regulated and let alone, flaunted and concealed. Christianity, the greatest moral force in the history of mankind, has repeatedly and systematically attacked it with a scourge in one hand and a balm in the other, but the effect has been trifling or transient. Nor have all the social and administrative resources of modern civilization availed to exercise an effective control. The elementary laws on which prostitution rests are stronger than the artificial codes imposed by moral teaching, conventional standards, or legislatures, and attempts at repression only lead to a change of form, not of substance. It survives all treatment, and although it may coëxist with national vigor, its extravagant development is one of the signs of a rotten and decaying civilization."

Today the problem presents itself for solution in our country surrounded by conditions which are peculiar to us as a people and in very marked manner influenced by them. We are essentially a commercial nation, and prostitution, which has been defined to be promiscuous unchastity for gain, has taken its place in our large communities as a business, organized and controlled by all of the conditions of the most legitimate system of trade which constitute our commercial activities. Its laws of supply and demand bring into play the energies of a class of debased men and women who have made the principal city of our country the centre of vice of the nation if not of the whole world. As a result of the investigations made by the Vice Commission in the City of Philadelphia it has been ascertained that from seven to twelve millions of dollars are spent yearly in that city in vice, and that there are in operation between 600 and 700 houses of ill-repute. It has become a glaring part of our political systems in our large cities, and has developed an association with the police departments of those cities which makes them the protectors of the most debased forms of vice, extortioners of blackmail procedures and graft thieving, who thrive on the unholy trade of the unfortunate social outcasts and share with them their hard-earned, ill-gotten gains. In addition it has stimulated the growth of the most degraded class that ever disgraced the name of man, the creatures who live upon the earnings of individual prostitutes with whom they cohabit.

Samuel H. London, the investigator of the White Slave Traffic, connected with the Department of Justice at Washington, states as a result of his investigation, that the income of the unfortunate women who support men on their earnings may be estimated to amount in the City of New York to the enormous sum of $57,000,000 a year. This total represents incomes approximating $2200 a year on the average, and large as it is, it represents, according to his investigations, only a part of the amount spent in a year in this evil way, as he concerned himself only with commercialized vice. In his investigations Mr. London found that, against the 26,000 known unfortunate women who support men in New York City, there are only 37,000 in the rest of the country, a total of 63,000 human beings living in a state of bondage the horrors of which it is difficult to appreciate. Six thousand men are engaged in the City of New York in the White Slave Traffic, and they procure women by the hundreds to send to other cities. These statements present an appalling picture of the state of morality which holds sway in this day, the beginning days of the enlightened twentieth century, in the principal city of our country and in a degree in all of our large cities.

The study of the causes of prostitution is now claiming quite universal attention in our country, especially with reference to the measures which should be taken to stop its continued growth, to secure eventually, if possible, its absolute suppression and the reform of the women engaged in the traffic. The history of prostitution shows clearly that there are many avenues leading into the life, the principal of which is indolence, the love of excitement, and hostility to restraint: the same causes which make members of the criminal classes. A large number, it is claimed, have the sexual appetite developed in an abnormal degree—of 3855 interrogated by M. Buls, in Brussels, 1118 admitted "*le gout pour l'homme.*" Among the assigned secondary causes are: (1) difficulty of finding employment, (2) excessively laborious and ill-paid work, (3) harsh treatment of girls at home, (4) promiscuous and

indecent mode of living among the overcrowded poor, (5) the aggregation of people in communities and places of employment where the young are brought into constant contact with vicious and demoralized companions, (6) the example of luxury, self-indulgence, and loose manners set by the wealthier classes, with the style of dressing of the women of the present day which rests on the borderline between the necessity of body drapery and indecent body exposure, and which in the male provokes sexual emotions and stimulates sexual appetite, (7) demoralizing literature and amusements with the absence of proper descipline in the home, (8) the arts of profligate men and their agents."

The American Federation for Sex Hygiene, at the meeting of the Fifteenth International Congress on Hygiene and Demography, September 23, 1912, presented through a special committee, a report on "Sex Hygiene," which contained the following statement: "In the United States there are 300,000 public prostitutes; 50,000 die each year, and 50,000 are added to the list in the same time. All are infected by venereal disease. For each public prostitute there are ten clandestinely immoral girls. The sources of these are department stores, factories, mills, offices, schools. Their way is through dance halls, picture shows, theaters, cafés, saloons, to the house of assignation. It is a short step from clandestine to public prostitution. Fifty per cent., or upward of 14,000,000, boys and young men contract venereal disease. Hundreds of thousands of innocent wives are infected by their husbands. Fifty per cent. of all sterility is due to venereal disease in the male." This statement was placarded on the walls of one of the halls in which public meetings for the discussion of sex hygiene were held. While it may be in a way true, it is too general to be accepted as entirely worthy of consideration from a scientific viewpoint.

Reference has been made above to the efforts which have, from time to time, been made in the history of prostitution to accomplish reclamation of the women who have entered the life. "The earliest attempt was that of the Roman Empress Theodora, wife of Emperor Justinian, quoted above, herself a prostitute in early life, who established a home for five hundred women on the Bosphorus. After a time they could not bear the restraint; some threw themselves into the sea, and eventually the scheme was abandoned." The experience of those conducting rescue homes is of the same character. Mr. London, who has been quoted above, states it as his belief that the percentage of unfortunate women who reform is less than 2 per cent.; not more than two women of this type out of one hundred reform. He further states that every effort to put down vice by stringent laws has failed, and plans to reform unfortunate women, while they have accomplished much good, have never been far-reaching in their results.

As an illustration of the failure of vice crusades, and the enforcement of stringent laws to accomplish complete suppression, attention is directed to the attempts made recently to drive vice from the city of Chicago. Resorts were closed and the women driven into the streets. Offers made by managers of rescue homes and civic welfare organizations to provide homes and occupations at good pay, as well as every possible facility to lead a moral life, were spurned. Some went to other cities, but fifteen hundred remained in the city, and their disposition became the real problem of the situation resulting from the crusade of the State authority. In another city, where a vice crusade was carried out, it was found that street-walking was greatly increased and tenement and apartment houses became the homes of the evicted women. In marked contrast, it is stated that in Copenhagen, Denmark, from 1871 to 1896, 33 per cent. of the registered prostitutes were removed from the register by marriage and by returning to friends.

In Japan, the Yoshiwara, which is the home of prostitutes, is a portion of the city set apart for their exclusive residence. Within its confines are parks and pleasure grounds, places of amusement, and a hospital, where they are sent for treatment, when the careful medical examinations which are made show that it is needed. Once admitted to the Yoshiwara, the inmate remains there during life or until removed by friends or by marriage. Filial obedience is a marked trait of character of the people, and the daughter of proper age willingly and cheerfully becomes an inmate for the money which is paid and which may be required to relieve the financial embarrassment of the father.

With the information which I have endeavored to place before you, the larger part of it taken from the work of those who have made the subject under discussion an earnest study, we are prepared to make an effort to solve the problem, not with any hope of doing more than will, in a way, improve present conditions, and suggest plans of adjustment which will secure a rational control of a distorted element of our social life which from the earliest days has been recognized as "an incurable evil." "Its ultimate basis," as has been truly said, "lies in the two most elementary attributes of living things, the will to live and the instinct of reproduction," and we must not ignore these attributes in any remedy which we may apply; accepting it as a part of the criminal life, great and small, which is an integral portion of our social existence, we must be content to accomplish in its treatment no more, no less, than is accomplished the world over in the treatment of crime. Murder, as an example of the highest type of crime, has existed since the days of Cain to the present time, and it may be asserted without the fear of successful contradiction that, despite all of the efforts for its suppression which our laws have included and our courts of justice have enforced, it will continue to exist until the end of time. This being true, it still behooves communities to protect themselves against its practice by such measures as will be effective in the control of those who may be impelled to commit it. The same may be said of prostitution, desirable as it may be from a moral point to completely destroy it at one blow, it is in the very nature of things impossible. To control it its existence must be recognized; it avails nothing to attempt to put it out of sight, to cover it with a veil of false sentimentality as something in the relief of which the pure and good should fear to lend a helping hand. Its social and its hygienic conditions demand the efforts and the help of the social worker, the well-balanced men and women who have studied it in its varied phases in their work, and the medical men who by their knowledge and training are equipped for the treatment of the diseased conditions which accompany it and which are so destructive, in their far-reaching results, to the welfare and well-being of the human race.

How shall these agencies be brought into effective

action? Any plan which may be adopted must include not only the control of the class, but the protection of those who constitute it. Under the general laws of cities and communities of our country prostitutes enjoy the same rights and privileges as any citizen, and become amenable to punishment and the infliction of penalties in the same manner as the citizens who may violate the law. They place themselves under the restraint of the law when the business they conduct or the life they lead may become hostile to the best interests of the communities in which they live. That prostitution is hostile to the best interests of the community is a self-evident fact, and it calls for restraint by the law which should be applied in a humane and rational manner. This would seem to be best accomplished through a commission authorized and appointed preferably by the State. The constitution of this commission is of paramount importance. In the number of its members there should be sufficient to include both men and women of experience and judgment, of well-balanced mentality, called from different occupations and professions of life—the man of business, the banker, the jurist, the lawyer, the physician, the experienced journalist in constant touch with the current events of the world, members of the ministry and at least two women trained in social work, who should be able to consider the questions involved uninfluenced by the emotions and with the unbiased judgment which good common sense confers. To a commission so appointed and constituted may be safely entrusted the formulation of such plans of care and control of the unfortunate class of social outcasts as will contribute to their betterment and to the protection of the community. Through this commission the blackmailing policeman and the grafting politician will be eliminated. With the powerful assistance of the National Government the White Slave traffic will be destroyed. Already in this direction a good beginning has been made, and the social and moral education of the people, beginning with the child in the home, where the true mother teaches both by precept and example, will contribute to the closing in large degree of the avenues leading to the life of prostitution. The commercial value of the brothel will be so minimized by the withdrawal of the sale of liquor in all forms and amusements of degrading character that the business will no longer be remunerative and the proprietors will retire to engage in some occupation of more respectable type. Representatives of the State and local boards of health should have official membership in the commission.

As the guardians of the public health our profession occupies a most important and a most responsible position in the protection of the community, and the subject of transmissible specific disease is, if anything, a greater menace to its welfare, through the far-reaching influence of hereditation, than the prevalent acute contagious and infectious diseases. The subjects of these diseases, the law, through the boards created under its provisions, takes control of, isolates them, restrains them of their liberty, and submits them to curative treatment. No valid reason can be urged against the maintenance of an assured freedom from disease of the public prostitute by compulsory medical examination and treatment under plans instituted by the commission. The beneficial effect of these examinations are well established by the history of prostitution, and they are conducted to-day in countries of the Continent of Europe.

Thus we conclude our study of a condition of our social life which closely concerns the betterment of the human race, shown by its history to be inseparable from human society in the large communities which our state of civilization produces. Violent crusades attempting its total destruction have been followed by reactions which have intensified its vicious elements and have greatly increased the difficulties of dealing with it so that its evil influences may be materially decreased. Its existence must be recognized, the veil of ignorance and false sentimentality which so imperfectly conceals it must be torn aside, and its treatment must be conducted in a humane and in a rational manner. Those who assume to undertake its treatment must be guided by the illuminating rays of the lamp of knowledge and experience which lead into paths guarded on all sides by well-defined and conservative methods of administrative procedure.

INFANT MORTALITY

By MARK S. REUBEN, M.D.,

NEW YORK.

ASSISTANT DISEASES OF CHILDREN, COLUMBIA UNIVERSITY.

INFANT mortality deserves more attention than it receives at present; it should interest not only physicians, but also sociologists, economists, and philanthropists. In the United States, infants under one year constitute 2.2 per cent. of the total population; in this 2.2 per cent. of the population occur 19.2 per cent. of all deaths. About 3,000,000 infants who are born alive do not live to celebrate their first birthday; this is the toll of death which the civilized world pays every year; in spite of this great loss of life, there is hardly any interest shown by the laity or by the general medical profession; if an equal number of stray dogs and cats were to be put to death, what a howl the whole world would raise; but this needlesss sacrifice of human life goes on without protest. The main reason of this indifference or lack of interest is ignorance of existing conditions. The subject of infant mortality is indeed a sad one when one realizes that 70 per cent. of the deaths are preventable, and that a large per cent. of the preventable deaths are purchasable; the reduction of infant mortality is indeed a subject for "dollar diplomacy."

In the registration area (1910), of a total death of 805,412 people, 154,373 (19.2 per cent.) were infants under one year; of 147,168 deaths in New York State (1910), 27,503 were infants under one year; and 16,159 of these occurred in New York City. Of infants who die under one year, 10 per cent. do not live 24 hours; 25 per cent. do not live 1 week; 35 per cent. do not live 1 month; 55 per cent. do not live 3 months; 75 per cent. do not live 6 months. (See Tables I and II.)

In Table 1, are enumerated the most important causes of death in infants under one year; for comparison are given the causes of death at all ages. It is evident that the important causes of deaths in infants under one year are diarrhea and enteritis, which cause 29 per cent. of all deaths, premature birth, congenital debility and injuries at birth, which cause 25.5 per cent. of all deaths; the respiratory diseases which cause 15.8 per cent.; malformations 4.9 per cent. and diseases of the nervous system 5.1 per cent. Of all the deaths recorded in the registration area from digestive disturbances, 47.4 per cent. occurred in infants under one year; it is

TABLE I.—DEATHS FOR REGISTRATION AREA (1910)*

	All Causes	All Ages	Per Cent.	Under 1 Year	Per Cent.
		805,412	26	154,373	9.2
I.	General diseases	215,692		14,250	1.0

XIV.	Ill defined causes	12,462	1.5		4.5

*Registration area=58.3 per cent. of total population.
=53,843,896 people.

also interesting to note that 85 per cent. of deaths from convulsions, 54.4 per cent. of deaths from pertussis, 51.5 per cent. of deaths from gonorrheal sepsis, 51.5 per cent. of deaths from syphilis, 24 per cent. of deaths from respiratory diseases, and 21.9 per cent. of deaths from tuberculous meningitis occurred in infants under one year.

A study of Table 2, shows that the most common causes of death under 24 hours, are premature birth, congenital debility, injuries at birth, and malformations. Under one week and under one month, the same are still the most important causes of death; it must be added that 50 per cent. of the cases that die from convulsions, do so before they are one month old, nearly all cases that die from prematurity, congenital debility, injuries at birth, and malformation, do so before they are three months old; the great causes of death after the third month are diarrhea and enteritis and the respiratory diseases.

Predisposing causes. Chief of the causes, which are conducive to this high infant mortality, is infancy itself; in infancy, all the organs and all the functions are at their lowest ebb; the resistance to outside influences, is small; males are more susceptible to death at all ages; and under one year more males succumb than females. Race and nationality are also important factors; infant mortality is least among Jews and highest among Slavs. The mortality differs in various countries and in different States of the United States. Of every 1,000 infants born alive in Chili, 326 die before they are one year old; in New Zealand, on the contrary, only 71 die. In the United States of 100 deaths of all ages 19 are infants under one year; this varies in the different States; it is only 11 per cent. in California and 24 per cent. in Pennsylvania. Color also predisposes, as infant mortality is much higher among the negroes than it is among the white people. City life is also conducive to a high mortality; in the cities of the registration area (1910) 21 infants of every 100 born alive died under one year, whereas only 18 died in the rural part of the registration area; this is mostly due to the greater density of the population in the cities; where the density is greatest there the air, the soil, and often the water, are liable to be fouled; infectious diseases are more rapidly and more readily spread, and indirect causes, as the greater abject want, filth, crime, drunkenness, and other excesses, are more prevalent. In the first week of life the city rate exceeds the country rate by 23 per cent., in the second week, by 64 per cent., in the third week by 83 per cent., and in the fourth week by 97 per cent., showing a progressive increase in deleterious effects of city conditions on infant life; deaths from congenital debility, are twice as fatal and deaths from diarrhea are seven times as fatal in the city as in the country. Meteorological conditions have a distinct effect on infant mortality; atmospheric heat above 73.4° F. has a distinctly injurious effect upon infants; other factors which affect infant mortality

TABLE II

	DEATHS UNDER						
	One Year	Under 1 Day	Under 1 Week	Under 1 Month	Under 3 Months	Under 6 Months	Under 9 Months
All causes	154,373	14,946 (10%)	36,351 (25%)	58,089 (35%)	86,235 (55%)	116,039 (75%)	137,810 (90%)
Premature birth	20,275	8,808	16,197	19,498	20,275	20,275	20,275
Congenital debility	15,361	2,007	5,943	10,273	15,254	15,317	15,347
Injuries at birth	3,725	1,740	3,430	3,689	3,725	3,725	3,725
Malformations	7,501	1,437	4,380	5,901	6,700	7,135	7,358
Convulsions	4,089	120	1,144	2,070	2,823	3,441	3,824

Respiratory diseases	24,375	54	886	4,094	9,169	14,545	19,288

are temperature of the dwelling, lack of sufficient cubic space per capita, improper ventilation, and amount of rainfall.

Heredity plays an important part in infant mortality; it acts both directly and indirectly; certain diseases, as syphilis, are directly transmitted to the offspring; in case of tuberculosis only the tendency to acquire the disease is transmitted; general debility of the parents means congenital debility of their offspring. Many nervous affections also are directly transmitted to the offspring; there are cases recorded of congenital smallpox, measles, scarlet fever, influenza, pertussis and typhoid fever. Of all diseases mental deficiency is most apt to be transmitted by descent; miscarriage, and stillbirths and infant mortality are much higher among idiots. The mortality of infants whose parents are alcoholics is very high; alcoholism leads to miscarriages and to prematurity; 50 per cent. of the children of drunken mothers are dead born or die within the first year; the infants of alcoholics are also often neglected; the daughters of such parents make poor wet nurses.

Neglect of the infant may be intentional or unintentional. In cases of mothers who are compelled to work to support themselves, and where the infant is entrusted to an older child the neglect of course is unintentional; also in cases of mothers who have six, seven or eight little ones, a few of them must be neglected; and it has been proven that infant mortality is very much higher in families where there is a rapid succession of pregnancies; not only must some be neglected, but a few of necessity must be brought up on the bottle; the mother's health also becomes undermined and in consequence this leads to birth of infants who are atrophic. Thus there is a vicious circle formed. It is sad but true that not a few infants die every year from wilful neglect on the part of the mother; most of these infants are of illegitimate birth.

The infant mortality among illegitimate infants is almost double that of the legitimate; it is said that three out of every four illegitimate children die before they are one year old and the fourth is destined to a life of crime or prostitution; it is these infants that make up the high mortality of large cities. Illegitimate infants form about 4 per cent. of the total births, but the deaths constitute from 25-30 per cent. of the total deaths of infants. Nearly 40 per cent. of infant deaths under one year in New York City occur in infants confined in institutions, and a great per cent. of these are illegitimate children.

Where illiteracy prevails, the infant mortality is correspondingly high. Ignorance on the whole is one of the most important of the predisposing causes; ignorance of the value of mothers' milk, ignorance of proper management of infants, ignorance of proper modification of cow's milk, where mother's milk is not available, all have an important relation to infant mortality. Poverty acts in many ways to maintain a high death rate; poor mothers must work till pregnancy is well advanced; they also must return to work soon after confinement; thus this leads to congenital debility of the infant, and the early return to work necessitates the infant to be brought up artificially; it has been demonstrated that good food and plenty of rest during pregnancy have a direct beneficial effect on the weight and health of the newborn infant; poverty also leads to unhygienic surrounding of the home; and it has been shown that infant mortality is higher in cases of families living in one room than those in two, and greater in the latter than in those living in three rooms. Many women who work in lead factories, are subject to frequent miscarriages; many deleterious effects have also been noted in pregnant women working in arsenic, phosphorus, and mercury factories; all these poisons may cause repeated abortions or premature birth of infants in gravid women.

Diarrhea and enteritis. Of the active causes diarrhea and enteritis are the most important; of the 154,373 infants who died under one year, in the registration area of 1910, 44,695 (29 per cent.) died of diarrhea and enteritis; the great majority of these deaths (over 90 per cent.) were in artificially fed infants. In the United States about 75 per cent of all infants are nursed and about 75 per cent. of all deaths in infants under one year occur in the 25 per cent. that are artificially fed; as 30 per cent. of all deaths are due to diarrhea and enteritis, it is evident that to reduce infant mortality from this cause we must reduce the number of infants that are fed artificially and that we must encourage maternal nursing in every case. Diarrhea and enteritis are almost entirely a problem of bottle fed infants. Poverty too helps to kill many infants from this cause. Many mothers who are unable to buy clean, fresh bottled milk, resort to condensed milk or loose store milk; deaths from diarrhea are most common in those using these foods. Diarrhea is most common during the summer months, but it is an important cause of death throughout the first year; during the first month of life, not so many die from this cause, mostly due to the fact that most infants are nursed at least two, three, or four weeks. Clean milk, education of mothers, and charitable aid to the worthy poor, all help to reduce mortality from this cause, but our main effort should be lent to make all mothers nurse their infants. Diarrhea is more fatal in cities than in the country, and is more dangerous to boys than to girls; it is also dependent on mean temperature, rainfall, and humidity. These factors with bad light, improper ventilation, and contaminated or injurious food make this disease the scourge of infants.

Premature birth and congenital debility. Of 154,373 infants who died under one year in the registration area (1910), 20,275 died of premature birth, and 15,361 of congenital debility. About 20-25 per cent. of all pregnancies result in abortions; about 7 per cent. of all infants born alive are born prematurely and about 4 per cent. of all pregnancies result in stillbirths; stillbirths are most common in luetic women; in fact 75 per cent. of all conceptions of syphilitic mothers result in death of the infants within one year of birth. Repeated abortions are usually due to displacements of the uterus, or endometritis and especially syphilis; also due to certain poisons as alcohol, lead, and arsenic. Prematurity is due to lues, chronic toxemias as Bright's disease, certain heart lesions, abnormal irritability of the uterus, and chronic toxemias arising from lead, arsenic, mercury, and alcohol. Hard labor in the last few months of pregnancy also tends to cause premature birth; other factors which may cause it are faulty environment, emotion, fright, and shock. Syphilis is the most common cause of stillbirth; other causes are toxemias as eclampsia, prolonged labor in contracted pelvis, certain diseases of fetus, and certain complications as prolapse of cord and

placenta prævia. Congenital debility appears to be a question of nutrition; the nutrition of the mother exerts an influence on the weight of the offspring; it is underfeeding in conjunction with overwork which causes congenital debility and a high death rate from this cause.

Respiratory diseases. In the registration area (1910), 23,113 infants under one year died of some sort of respiratory disease (4,151 of acute bronchitis, 8,443 died of pneumonia, and 10,593 of bronchopneumonia). Deaths from respiratory diseases are far more frequent in artificially fed infants than in breast fed. Bronchopneumonia secondary to measles and scarlet fever is very rare in breast fed infants under one year; although not very frequent in artificially fed infants under one year, it is far more common in the latter than in the former. Nursing infants seem to have an immunity to the exanthemata; but this is not true of diphtheria and pertussis.

Tuberculosis and lues. In the same area, 2,416 died of tuberculosis; of which 923 died of pulmonary tuberculosis and 1,020 of tuberculous meningitis; tuberculosis is not transmitted directly to the infants; only a predisposition to this disease is transmitted; the majority of these infants become infected from their parents or other cases of tuberculosis at the house after birth; it is usually due to carelessness and neglect; only very few cases contract this disease from the milk. With lues it is otherwise; here the infants are directly infected before birth; lues causes the death and expulsion of the fetus in 50 per cent. of the pregnancies of such women; it also causes 10 per cent. of all pregnancies to terminate prematurely; so that although lues caused the death of 1,658 infants born alive, it is a far more important cause of infant mortality than these figures would indicate. Seventy-five per cent. of all pregnancies, of luetic women result in death of the fetus and infants before they are one year old.

The Contagious Diseases.—Infants under one are not very susceptible to contagious diseases; artificially fed infants, however, are more so than are breast fed. Pertussis is the most fatal of these diseases among infants under one year; in fact, pertussis causes more deaths in infants under one than measles scarlet fever, and diphtheria together. More than 50 per cent. of the deaths from pertussis occur in infants under one year old. The precautions taken to prevent the spread of this disease are very inadequate, and isolation of the afflicted is seldom carried out. There is no doubt that deaths from pertussis could be reduced 50 per cent. if the same stringent laws were to be applied to pertussis patients that are applied to measles, scarlet fever, and diphtheria patients.

Malformations.—It is doubtful if we can prevent malformations; in the registration area (1910) 7,501 infants under one year died of malformations. Seventy-five per cent. of all congenital malformations are those of the heart; it has recently been shown that lues is not a cause of such malformations; lues, however, is responsible for a certain number of cases of hydrocephalus. Diseases of the endometrium may also cause malformations.

Convulsions.—Many deaths are reported as due to convulsions. Convulsions are a symptom and not a disease; of the 4,089 cases of death due to convulsions, 2,070 (50 per cent.) occurred in infants under one month; these cases are mostly due to cerebral injury during labor, and the convulsions are only a symptom of the cerebral disturbance. The remaining cases occur mostly in artificially fed infants; here the convulsions are of gastrointestinal origin, and with tetany are usually associated in infants that have rickets.

Injuries at Birth.—Deaths from injuries at birth are mostly preventable; in 1910, 3,725 infants died from this cause; over 3,000 of these died before they were one week old. Injury at birth means lack of obstetric knowledge. When we realize that 50 per cent. of all women are delivered by midwives, it is not at all surprising that so many infants lose their lives from this cause. Many infants also die from infections of the cord, and general sepsis; also sepsis from circumcision, at the hand of professional "mohels." That society should tolerate such abuses is bewildering; if barbers should insist on treating gonorrhea, what a protest would be raised; but midwives may put their unclean hands into a uterus with impunity.

Other Causes.—Infanticide is not as common here as it is in England; deaths from overlying are quite numerous; such deaths occur most frequently on Sundays and Mondays, and they are not infrequently due to the stupor of drunkenness.

Résumé.—Before speaking of the means we possess to combat this enormous mortality, we must consider which diseases are preventable and which are not. Diarrhea and enteritis are mostly preventable, as they are diseases of artificially fed children, and are usually due to lack of breast milk and to the use of unclean cow's milk, condensed milk, patented foods, and improper modification of milk; it is a disease of cities, and is most prevalent in the hot summer months. Premature birth is also largely preventable, as it is due to chronic toxemias and other preventable causes; as cogenital debility is mostly a question of underfeeding and overwork of the mother, these cases, also, are mostly preventable. Injuries at birth should not occur if one understands obstetrics; convulsions as a result of injury to infants during labor are therefore preventable; convulsions of gastrointestinal origin are also preventable, for they occur almost exclusively in artificially fed infants. Tuberculosis and lues are certainly preventable. Lues is amenable to treatment and every luetic woman should be treated before conception. Infant deaths due to erysipelas, tetanus and hemorrhages are also mostly preventable. Deaths from the contagious and respiratory diseases and from meningitis are far more common in artificially fed infants, and therefore to a certain extent preventable. We see therefore that 65-70 per cent. of all deaths are preventable, and in preventing deaths from these causes we have an ample field for doing much good.

Reduction of Infant Mortality.—In studying the rate of infant mortality it is necessary to have accurate statistics; it is most important to have complete registration of births, for it is only from such statistics that any conclusions can be drawn. In the United States only five of the ten largest cities have fairly complete registration of births and deaths. In New York City there were less births recorded in 1912 than in 1911, showing that even here many births are not recorded. The records of deaths, of course, are far more accurate, as no burial can take place without a permit. As the rate of mortality can be studied accurately only by comparison with the number of births, the necessity of complete birth registration is evident; some European countries go to the extreme of paying doctors 25 cents

every time they record a birth; failure to report births should be punished by law; studying infant mortality without accurate data is like managing a steamer without a compass—we cannot tell where we are, nor what progress we are making.

Some one has remarked that infant mortality is a question of motherhood, and in a broad sense it is true; if every mother could be healthy and well nourished during pregnancy, and could be confined by a well trained obstetrician, and if she could nurse her newborn infant for eight months, then we would prevent the majority of infant deaths. To give birth to a viable infant the mother must be in good physical condition at time of conception. There is a movement now gaining popularity which recommends that only the healthy should be allowed to marry; it is suggested that with the marriage license each should present a medical certificate, stating that they are of sound body and mind; such a suggestion, if carried out, would result in much good; not only would it lower infant mortality, but it would diminish insanity, idiocy, drunkenness, nervous diseases, syphilis and many other diseases which are transmitted; of course, persons suffering from a disease which is apt to be transmitted to offspring should be allowed to marry, provided they undergo an operation of some sort which will sterilize them. But this is a beautiful dream, and the time when this idea will prevail in fact is far away.

At the infant milk stations one very frequently meets women who are married nine, ten or eleven years, and who have gone through as many pregnancies; many of these children are dead; the infant mortality in these families is out of proportion high; the rapid succession of births exhausts the mothers and compels the infants to be brought up artificially; many of the infants on account of the exhausted condition of the mothers are born atrophic and prematurely; many of these infants are unwelcome visitors; the remedy is simple; it is easy to suggest, but it is hard to carry it out; when one speaks to these mothers they say it does not depend on them, and in the majority of cases it does not. When such mothers ask a physician what can they do to prevent conception, it is futile to tell them not to have sexual intercourse and expect them to heed one's advice; nothing that the doctor may say will make such intercourse unpopular with the poor and the ignorant whatever the consequences may be; this is a subject which most physicians dread to touch upon, but it is a real live subject which must be solved. There is no reason why a physician should not advise a woman (where there are proper indications) how to prevent conception; such advice may save the lives of many mothers as well as of many infants.

Every woman soon after marriage should consult an obstetrician; it is the duty of the physician to examine the pelvis, the uterus and the adnexa, the heart and the kidneys of every woman who is about to become a mother, to see if there be any contraindications to childbearing; if there be any displacements of the uterus, such should be corrected; if pelvis is contracted, induction of labor two or three weeks before term should be advised; the breasts should be examined, and any abnormalities present should be corrected so that the newborn infant may nurse.

Poverty often compels pregnant women to work during the whole pregnancy; this has a very deleterious effect not only on the mother but also on the infant; infants grow most in the last months of gestation; in this period they gain 4 pounds in weight (from 3½ to 7½ pounds). It has been shown that of 500 mothers who worked till day of labor, their infants at birth weighed 3,000 gm.; of 500 who spent the last few months in a hospital, their infants weighed 3,290 gm.; and 500 who spent the whole pregnancy at the hospital, their infants weighed 3,308 gm. Poverty also causes many gravid women to be undernourished, and undernourishment of the mother means congenital debility of the infant. Undernourishment and overwork are therefore the greatest causes of prematurity and congenital debility. Laws should be enacted which prevent the engagement of pregnant women, especially those well advanced in pregnancy, and especially no gravid women should be allowed to work in lead, arsenic, phosphorus and mercury factories, as these poisons are very apt to cause miscarriages and premature birth; such laws have been enacted in England, but they are mostly dead letter laws. Charitable organizations should provide sufficient food to pregnant women who are in need; it would be ideal to send every gravid woman to a maternity hospital, to stay there during the whole course of pregnancy, but that is not possible through lack of accommodation and it would be impracticable, for many of these mothers have four, five and six other little ones to take care of at home. Charitable organizations should also take care of women after confinement, who cannot support themselves, so that they may be able to nurse their infants. Women should not be allowed to do wet nursing whose infants are less than six months; in France there is such a law. In France also, Henry Coulette and his wife, who lost their only child, started five restaurants, where all nursing mothers can receive three meals a day; at these restaurants the women are not subjected to any cross-examinations; all that is necessary is to have a nursing baby with you, and you are welcome to the food.

To prevent the many deaths from diarrheal diseases, we must conserve mother's milk; if every mother nursed her infant, we would save 80 per cent. of the infants who die of diarrhea and enteritis. Ninety per cent. of the deaths from diarrhea occur in 25 per cent. of the infants that are artificially fed. When one realizes what a life-saving measure mother's milk is, one is bewildered for what inadequate reasons infants are taken from the breast and put on the bottle; artificially fed infants do not only die from diarrhea and enteritis but are more susceptible to death from all causes; bottle fed infants have not the resistance of the breast fed. Diarrhea and enteritis are far more frequent among the poor bottle fed than among the rich, and this shows the influence of ignorance and poverty on infant mortality. The poor cannot afford to buy clean milk, they usually buy condensed milk or loose store milk; their ignorance makes home modification faulty, and the dirty, unhygienic surroundings of the home all tend to increase the number of deaths from diarrhea among the poor. Recognizing that many mothers can not or will not nurse their infants, milk stations have been established; these stations supply clean, pasteurized milk, and teach the mothers how to prepare the milk for the infant. The nurses connected with these stations visit the homes of these mothers and teach them hygiene of the baby and also inculcate in these mothers the necessity of cleanliness in the home;

that these stations have a tremendously good influence the statistics have shown, and their especial benefit has been the great reduction of deaths from diarrhea. Some object to milk stations because they may further artificial feeding; this is far from the truth; many mothers who brought little babies to the stations have other infants now, which they nurse; the great value of mother's milk is impressed on all of them.

It was in 1892 that Budin organized at the Charité the first consultation for nurslings; in 1894 Dr. Léon Dufour established the first *goutte de lait* at Fécamp; in England the first milk station was established in 1899 at St. Helen's in Lancashire. In New York City, milk modified and pasteurized was dispensed in summer to sick babies at the Essex Street Dispensary in 1891; one year later Straus founded his laboratories; since then many societies have united and formed the New York Milk Committee (incorporated 1910), whose purpose is to create through education and publicity a public demand for a clean and safe milk supply for all, and to prevent unnecessary loss of infant life. In New York City, in 1908, a division of child hygiene was formed; in 1911, the Association of Infants' Milk Stations was formed so as not to duplicate the work of different organizations maintaining milk stations; in all there are seventy-nine stations in New York City which take care of about 16,000 infants; fifty-five of these stations are under the control of the Board of Health. In 1909 a "Little Mothers' League" was organized; it consists of older school children, to whom lectures are given on the necessity of clean milk, home sanitation, management of an infant, etc.; this information is of great service to these girls, as many of them have to take care of infants while their mothers are working. In England there is a "Mother's League" where mothers receive above instruction. For a bottle baby to thrive the milk must be clean and fresh; one writer has estimated that clean milk is three times more valuable than education; this may be true, but both are indispensable. In New York City about 2,500,000 quarts of milk are consumed every day; this milk is supplied by seven different States; only 1 per cent. of this milk is certified or guaranteed; in Chicago nearly all the milk for infants is bottled and 75 per cent. is pasteurized. Only certified milk should be used for infants. It is the duty of the milk companies, which grant certificates to the milk producers, to look after the hygiene of the dairy, as it relates to the production and distribution of the milk; they also have the veterinary supervision of the herd, and the medical supervision of the employees, and they also examine milk chemically and bacteriologically.

Education, like charity, should begin at home; before we attempt to teach mothers and their daughters we should teach ourselves and learn the value of breast milk, and the proper modification of clean cow's milk where breast milk is not available. Many physicians do not realize that there is such a tremendous infant mortality, nor do they realize the life-saving qualities of mother's milk—if they did they would not take infants from the breast for very inadequate reasons. It is amazing, also, how many physicians recommend the use of patented foods; of 200 feeding cases that came to my notice at the Vanderbilt Clinic Infants' Station, where the feeding was previously prescribed by a physician, only thirty-eight ordered fresh milk and made any attempt at modification; 162 ordered one or the other of the patented foods. The significance of this is clear: rather than attempt to modify milk, they find it easier to advise this and that food, and advise to follow the directions on the package. Pediatrics on the whole and infant feeding in particular receives too little attention in the curriculum of the medical colleges; one-fifth of all deaths occurs in infants under one year, why should not a corresponding importance be given to pediatrics at the medical school? At this time when so much is being done to lower infant mortality postgraduate lectures on infant mortality and infant feeding should be given to all doctors who wish to come; much good can be accomplished from this.

Day nurseries, unless well managed, may be the source of disease and death of many infants; they are often the origin of many infectious diseases; although all of them are under the nominal supervision of the Board of Health, many of them are regular hotbeds of disease; unless supervised by trained nurses, they should not be allowed to exist; it is remarkable how carelessly many physicians examine children brought to them for examination for a certificate of health for a day nursery. Permits are also issued to certain women to board babies; here too much harm may arise, unless carefully supervised; many of these babies are deserted, mostly illegitimate, and there goes on a traffic in babies which is real. In New York City, about 40 per cent. of the infant mortality occurs in institutions; depending on the institution, the mortality varies from 40-90 per cent. of the inmates; there was a time when admission to an infant asylum meant "He who enters here must leave hope behind"; conditions are not much better now; the only hope of relief from this source is boarding babies in reliable homes, under supervision of doctors and trained nurses; this is better carried out in the suburbs than in the cities.

Many thousands of babies lose their lives through lack of obstetric knowledge on the part of doctors and midwives. Fifty per cent. of all confinements are conducted by the latter. Is it a wonder that the mortality from this cause is high? It is surprising that it is not higher. Midwives should have no standing in a civilized nation; they are a relic of antediluvian days; why should we permit this abuse in cities where well trained medical students under proper supervision, could well do the work? Of course well trained midwives are better than untrained, but at best they are a menace.

"A little knowledge is a dangerous thing;
"Drink deep; or taste not the Pierian spring."

Like pediatrics, obstetrics receives too little practical attention at the medical schools. When many professors of obstetrics admit that they are unfit to practice surgical obstetrics, what can one expect of the general practitioner? The facilities for practical instruction at most colleges are very inadequate. If all the aborted, the stillborn and dead through birth injuries, and sepsis, and the blind could raise their voices against midwives what a howl they would raise!

Advertising pays; and advertising or disseminating knowledge on infant mortality and means of reducing it must bring good results. A few years ago the Great White Way was resplendent with an electric sign advertising a religious movement; the results more than paid for the advertising; it is the best way of presenting the facts to the public; a

thorough advertising campaign kept up all year should be instituted; before we can expect the laity to co-operate, they must know the problem. Recently a national association with this object in view was formed; much good has already resulted, and much more can be expected. At the third mid-year meeting of the American Academy of Medicine, specializing in medical sociology, a conference on prevention of infant mortality was held November, 1909; in pursuance of the recommendation of this section a society was formed by the name of "The American Association for Study and Prevention of Infant Mortality." The object of this association is the study of infant mortality in all its relations; the dissemination of knowledge concerning the causes and prevention of infant mortality, and the encouragement of methods for the prevention of infant mortality.

Infant mortality, after all, is a question of motherhood, and in conclusion we may say with Saleeby: "There is no State womb, there are no State breasts, there is no substitute for the beautiful reality of individual motherhood."

"A mother is a mother still,
The holiest thing alive."

AUTHORITATIVE DIAGNOSIS OF GONORRHEAL STOMATITIS.

By JOHN BETHUNE STEIN, M.D.,

NEW YORK.

Cases of gonorrheal stomatitis have been reported from time to time in dental and medical journals. The purpose of the writer is not to disprove the occurrence of gonorrheal stomatitis, but to indicate how difficult and obscure is the diagnosis if the disease occurs.

The perplexities in determining whether or not an infection is gonorrheal depend not only upon the locality from which the discharge or exudate is taken for examination, but also upon the several methods employed in the examination and demonstration of the presence of the gonococcus. In cases of acute urethritis the morphology, grouping, and staining qualities of the microorganism causing the disease are usually sufficient to make a diagnosis; since the number of cocci in the urethra, resembling the gonococcus, are few, but for a definite diagnosis of the gonococcus the presence of the biological characteristics must be found. Prudden[1] says: "Inasmuch as one or more forms of cocci and diplococci occurring in the normal and inflamed urethra are morphologically similar to the gonococcus, great caution should be exercised in doubtful cases in deciding upon the nature of suspicious microorganisms in urethral discharges or other exudates." This statement is especially true in determining the presence of the gonococcus in discharges or exudates coming from the mouth, pharynx and nose of a patient supposedly suffering from gonorrheal stomatitis, because a number of cocci and diplococci resembling the gonococcus have been found in these localities.

Before the discovery of the gonococcus a gonorrheal infection was recognized by the anamnesis and clinical signs. At the present time the finding of a living contagium plays the chief rôle in the diagnosis. The discovery and careful observation of a number of microorganisms, which are united by a close genetic relationship, have taught us that many of the morphological and biological characteristics which were formerly considered as attributes of the gonococcus belong to a group of cocci. The fact that the meningococcus, together with similar forms of cocci, are to be found in the secretions of the nose, must occasion much caution in interpreting the finding in these secretions of the gonococcus. It is well known that the meningococcus is a saprophyte of the nose and pharynx. With the exception of the gonococcus the specificity of the microorganisms resembling the meningococcus has not been proved.

Von Lingelsheim,[2] during the course of an epidemic of cerebrospinal meningitis in Silesia in 1904-1905, found that discharges from the nose of patients having this disease contained, in addition to the meningococcus, six other cocci which closely resembled it and which could only be distinguished from it by cultural methods.

The morphological and staining characteristics of the meningococcus and gonococcus are very nearly alike and it is only possible to distinguish them from each other by cultural methods, so that the facts demonstrated by von Lingelsheim are of great use in detecting the gonococcus.

The following table which I have compiled shows not only the morphological, staining, grouping, and cultural characteristics of the gonococcus, meningococcus, and six other cocci which were observed by von Lingelsheim in the discharge from the noses of patients with cerebrospinal meningitis; but also, the important fact demonstrated by von Lingelsheim[3] that each one of these microorganisms causes, when cultivated upon sugar-litmus-serum-agar-media the fermentation of either one, two, all, or none of the following carbohydrates, viz., dextrose, levulose, and maltose. This matter of fermentation, as shown by the chart, is an important factor in differentiating these several cocci.

The gonococcus is afforded ample occasion to infect the mouth by objects (the fingers, eating and drinking utensils, etc.) which have been contaminated by gonorrheal discharges and exudates, coitus per os, cunnilingua, and the exudates of a gonorrheal ophthalmia passing through the nasal duct into the nose and thus into the pharynx and mouth. How often is the mouth infected by gonorrheal exudates or discharges? The futile attempts by Diday[4] to infect the nasal mucous membrane by discharges from cases of acute urethritis are well known.

Some writers claim the disease has been proved to exist in children. According to Dr. Victor Mucha,[5] Docent at Finger's Clinic in Vienna, a case of gonorrheal stomatitis has not been seen at Finger's Clinic during the past sixty years, and there has never been a case recorded in the obstetric clinic, pediatric clinic, or foundling asylum in Vienna.

In a recently reported case where an individual who had coitus per os with one who had an acute gonorrheal urethritis, shortly afterward developed a stomatitis, the diagnosis of gonorrheal stomatitis was made, but apparently upon the sole basis and authority of the "post hoc ergo propter hoc."

The suspected gonorrheal stomatitis cases may be grouped as follows:

(1) Cases reported before the discovery of the gonococcus.

(2) Cases where only a microscopical examination was made and the exudate revealed a microorganism which resembled the gonococcus in its

THE DIFFERENTIATION OF SOME GRAM-NEGATIVE DIPLOCOCCI POSSIBLY OCCURRING IN THE MOUTH

Characteristics	Morphological, Staining, Grouping, Etc.	Cultural		Fermentative:—(Grown Upon v. n Lingelsheim Sugar-Litmus-Serum-Agar-Media) Capability of Causing Fermentation of		
		A	B	Dextrose	Levulose	Maltose
1. Gonococcus	Gram-negative diplococcus; may appear in tetrad form; found extra and intra cellular	Rarely grows upon ordinary agar	Upon serum-agar the colonies are more or less round, delicate and gray, and can be scarcely distinguished from those of the meningococcus; when the colonies are older they have a "lobe-like" border	+	−	−
2. Micrococcus meningitidis cerebrospinalis	Gram-negative diplococcus; usually appearing in tetrad form. Found extra and intra cellular. Morphologically very similar to the gonococcus; in cultures there are great differences in the cocci	Difficult to obtain cultures. As a rule it grows upon serum-agar	Upon serum-agar the colonies are very delicate, grayish translucent with smooth edges. Under the microscope (Leitz 3. Ocular 1.) The colonies appear homogeneous and have a dirty light yellow color, the edges are smooth and somewhat wavy	+	−	+
3. Micrococcus catarrhalis. (R. Pfeiffer) (Diplococcus pharyngis communis)	Gram-negative diplococcus. Found extra and intra cellular	Grows upon ordinary agar	Forms upon serum-agar round, white, compact colonies with dry, uneven surfaces and usually irregular edges. When examined by a low-power lense the colonies appear brown and granular	−	−	−
4. The diplococcus pharyngis siccus	A fine gram-negative diplococcus	Grows best upon blood-agar	Upon blood-agar the colonies may have a diameter of 3 m.m. After some days their surfaces become dry, firm and wrinkled; so that they cannot be completely broken up when shaken in a fluid medium	+	+	+
5. Micrococcus cinereus	A plumper gram-negative diplococcus; the cocci usually forming themselves in discrete masses	Grows upon ordinary agar	Forms upon serum-agar small round gray or grayish white colonies. Under the microscope the colonies appear brown, coarsely granular, and have smooth borders	−	−	−
6. Diplococcus pharyngis flavus I VVV	A gram-negative diplococcus. Very similar to the meningococcus. Seldom appears in tetrad form	Grows upon ordinary agar	Forms upon serum-agar roundish slightly raised grayish yellow colonies, which are sometimes difficult to distinguish from colonies of the meningococcus	+'	+	+
7. Diplococcus pharyngis flavus II	A very small gram-negative diplococcus. Resembles the micrococcus catarrhalis	Upon serum-agar it forms colonies resembling those of the micrococcus catarrhalis	Colonies grown upon a blood-serum medium or Löffler's serum appear golden yellow	+	+	+
8. Diplococcus pharyngis flavus III	A gram-negative diplococcus of the size and appearance of micrococcus meningitidis. Does not form tetrads	Does not grow upon ordinary agar	Forms upon serum-agar, round, slightly raised, yellow translucent colonies, which when examined by a low-power lense are very similar to those of the meningococcus. A pure culture is light yellow	±	−	±

+ = Fermentation. (The culture medium is colored red.)
− = No fermentation. (Growth appears blue.)
+ = Not marked, but good evidences of fermentation.
± = Doubtful or slight evidences of fermentation.

morphological, staining, and grouping characteristics.

(3) Cases where, in addition to the microscopical examination, cultures upon agar and serum agar, were made in order to find the suspected microorganism, the findings proving the presence of an organism resembling the gonococcus.

(4) Cases where, in addition to the microscopical examination and cultivation of the suspected microorganism upon agar or serum agar, proving its resemblance to the gonococcus, the suspected microorganism when grown, upon von Lingelsheim's sugar-litmus-serum-agar-media shows the essential characteristics of the gonococcus.

In the diagnosis of gonorrheal stomatitis we may invoke the "post hoc ergo propter hoc" theorem, but we must also demonstrate the morphological, staining, grouping, and ordinary cultural characteristics of the gonococcus, and then verify our conclusion by the use of the sugar-litmus-serum-agar-media of von Lingelsheim.

Trigger-Knee.—M. H. Billet applies the name "genou à ressort" to a rare condition which has been described by R. Jones under the name of trigger-knee, and by Thiem under the name of "schnellendes Knie." The condition is characterized by a sudden arrest of the movement of the knee during flexion or extension; this arrest is followed by a sudden jerking and lateral movement of the leg and the production of a clicking sound. The condition is distinct from that of displacement of the semilunar cartilages of the knee, and is apparently the result of a laxity of the joint capsule, usually traumatic, but sometimes of congenital or inflammatory origin—*Gazette des Hopitaux.*

A GLIMPSE OF INDIAN HOSPITALS.*

By C. B. MEDING, M.D.,

NEW YORK.

EXECUTIVE SURGEON, THE HARLEM EYE, EAR, AND THROAT INFIRMARY

In any useful survey of the world's hospitals there are three things to be preconsidered and appreciated. They are the environment, the need, and the resource. While beauty and utility should ever be combined, it often happens that the sole beauty is the wise and resourceful utility; and again one may see many examples where most attractive beauty is utterly divorced from usefulness. Where large sums of money have been bestowed for specific purposes, compelling expenditure within limits, we naturally find great outlay in site and architecture, but any critical professional opinion must discount mere extent and elaboration as items for commendation.

Again the reader must bear in mind that hospitals, like persons, being of different generations, must be judged in their time. The same adjectives may be used for all, but one must mentally modify the value with the factor of age. I believe, too, that the element of economy should enter into the criticism. We of the West have run largely to extravagance. The combined influence of ambitious architects, lay purses, and persuasive hospital supply manufacturers has often converted simplicity into luxury, and elaboration of detail has been accepted as necessary convenience. Very largely the profession has given over or been pushed out of the managerial departments and have neither vital part nor knowledge of the balance sheet, details of architecture, household management, culinary and clerical departments, entrance, discharge or convalescence of patients. All these have fallen into the hands of specialists and the institutional has supplanted the individual. This evolution has relieved the physician of much labor and worry, but I am not at all sure that it has universally brought economy or wisdom to the work, or comfort to the patient. While some of these changes have occurred the world over, the physician still holds a much more important place in the medical institutions of the old world, and in newer territory, speaking from the hospital standpoint, the result is evidenced in ways delightful to the traveling brother. Environment and resource have been great factors in the hospital problem of India and the Far East (of the first of which I am best prepared to speak) not only in construction, but in management.

In the first place India has a great natural sterilizer in the sun. But for this the population of India had long ago ceased. When we consider the disease of that continent—one long history of smallpox, cholera, consumption, and, in later times, of plague; the lack of knowledge in any class; the utter ignorance and superstition of almost all; the poverty, recurrent famine, drought, and inherent fatalism—we shall see that any power less mighty than the solar heat had been and would be futile. Of course, of knowledge of its beneficent action there was none. No one knew that, because a gonococcus could not outlive a higher temperature than 108 degrees Fahrenheit, he ceased from troubling, nor that the search for coolness was constructing buildings upon which and through which the sunlight and sun-purged air might bring sanitation. Open sewers were easiest—the sun permitted them.

I have seen the servants empty the fluid contents of the latrine or drain on the soil just without the compound at 7:30 A. M., causing considerable slop and odor. At 8:30 I have walked over the spot on dry, odorless sand. Should the beds, simple string beds called "charpoys," become bugridden or otherwise unclean, they are scrubbed and put out in the sunlight. India is a dusty country. It takes half the night for the day's dust to settle, yet the use of dung for fuel reduces this constituent of the atmosphere tremendously, and the millions of birds, large and small, keep the land clean. That the sun can and does give so great service is no excuse for much that exists in India, but it is a reason why much has been done that under other circumstances would have been impossible.

Many Indian hospitals are one-storied buildings, extending over much ground, surrounded by liberal spaces, bare or parked. In these, as in higher buildings, each floor has its enclosing galleries which are frequently, and, in some places, always, utilized as wards. The separation of sexes, religions, and sometimes castes, often necessitates strange and troublesome ordinances. Screened doors are largely used, also the punkah, now often operated by power. The gasoline and electric fan are also in common use. In Bombay, Madras, Calcutta, Delhi, Lucknow, and Lahore, one finds training schools and a fair supply of native nurses, but in the smaller places—and India is made up of small places—the staff is of the fewest and attendants of the humblest; the chief nurse or matron being often a missionary or a Sister. Wonderful women these, whose untiring devotion irradiates outlandish places with happiness and service. Considering the training, the variety of language, religion and caste, the often paralyzing fatalism and the blinding superstition, the efficiency is remarkable.

Aside from those hospitals which are wholly or in large part individual gifts or memorials, such as the Jamsetjee Jeejeebhoy Hospital at Bombay, the Eden and Dufferin Zenana Hospital, wherein the nursing is under the Sisters of St. John, at Clewer, and the Ezra Jewish Hospitals of Calcutta, the Dufferin Hospital of Rangoon, and those begun and maintained by the missions, some fifty in number, the average city or town hospital is founded by equal gifts from government and residents, and thereafter supported by resident or local board. In the great cities such hospitals are on about the same footing as are our own. Where there is wealth and age there is abundance, where there is poverty there is struggle. The general hospital at Madras, whose records reach back to 1829, is one of the largest and finest to be seen anywhere and supports 500 beds. The ophthalmic hospital of that city, under Colonel Eliot, is, I should say, the equal of any in the world in location, construction, and equipment. Nothing is missing from the simplest device to the latest instruments of precision and demonstration. The woman's hospital is likewise imposing and up to date. There are besides, throughout India, many dispensaries, but they include a large quack element.

I think that on the whole less work is done in the large centers, in proportion to their equipment. Many mission hospitals housed in simple low brick buildings, unplastered and affording little more than a shelter for beds, teem with patients. With few exceptions there is practiced an economy of which we can scarcely conceive, any account of which, my own experience tells me, is likely to

*Read before the Bronx Medical Society, March 12, 1913.

prejudice and misinform. It was not until I became acquainted with the reason and result that I valued properly the splendid thrift and care that made the work possible. In some places, as here, influence and wealth provide generously, but for the most part the armamentarium is limited to usefulness. Operating rooms are large and airy, but sparsely furnished; the sterilizing is effectual, but never complicated. The economy in dressing, drugs and paraphernalia is startling. Douching with the bichloride 1-2000 is the common cleanser of India, many surgeons virtually working under it, and whatever may be the scientific conclusion or personal preference, observation shows it to be satisfactory. A visit to the hospital apothecary shows similar wise selection of simples, and a wholesale elimination of experimental preparations. I am not sure but that the directness and definiteness of the medication practised by Anglo-Indians has much to do with their high therapeutic confidence and excellent results. There can be no doubt that the constant exhibition of new remedies, knowledge of which is largely limited to the advertisements of manufacturers, replaces to an excessive degree that study based on the physiological effect of known elements. Much medical cynicism emanates from the use of remedies that are to most of us little more than names, a use so prevalent as to be dangerously near hysteria. Of this the faraway physician is apt to be innocent. I learned much of the value of mercury, opium, arsenic, quinine, aloes, rhubarb, and the salicylates in a country in which a multitude of petty drug and pharmacal companies could not provide physicians with samples of these remedies. All this is equally true of instruments, dressings, utensils, and furniture.

India is as yet comparatively poor, especially poor in money and more particularly poor in the distribution of the money it has. Consequently the running expenses of hospitals must be low. There is besides a good deal of antagonism. The native stone doctor, the drug vender, the worthless midwife, and the lens coucher, resident or itinerant, are not friends of the hospitals, diplomas, or licenses, and they are numerous and vociferous. Hence, even where there are *x*-ray outfits and laboratories their use is limited and the dependence is largely on diagnosis made from signs and symptoms. Whatever the loss, one thing is surely gained. The men are expert in observation, examination, and sound logic. They are, too, all round men. We saw the obstetrician perform cataract operations, the general surgeon treat typhoid fever, and the ophthalmologist make careful autopsies.

No account of hospitals would be complete which did not mention the swiftness and precision of their operators. In general the Anglo-Indian operators are opposed to long anesthesias. Several told me that with Indians, at least mortality and lengthy anesthesias run hand in hand. We have not been without our rapid operators, neither has England nor the Continent, and they have all been insistent on the value of speed. It is certainly a matter worth considering, and since it may be acquired, need not interfere with thoroughness, and is logically advantageous, I believe we should cultivate it. Especially most of us can save time by directness and by the use of those minutes so frequently devoted to change of mind, instrument, and position.

Indeed, the amount of work, lack of assistance, and scarcity of good men and accommodations is a constant incentive to the Anglo-Indian surgeon. Time will correct these conditions. Bombay, Lahore, Lucknow, Calcutta, and Madras have medical colleges and there are many other places and sources of education. I believe the numbers of natives annually added to the profession will be above the average. The courses are long and hard, the practical work demanded is arduous, and the amount and variety of clinical material is unsurpassed.

I would like to give at least a partial picture of one very useful hospital, the surgical hospital at Amritsar, in the Punjab. It was there that the writer studied the Indian cataract operation under its originator, Colonel Henry Smith, I.M.S. This hospital consists of four pavilions which form the sides of a quadrangular park. Its capacity is three hundred beds, and its daily average of patients is about fifty in excess. Two of these long single-storied brick buildings consist of two wards opening through numerous high doorways on either side to galleries, whose cover is the extended main roof. Four or five steps lead to the ground and there is no enclosure other than the columns that support the roof. In one of these, the central part, double the height of its wings, is contained the operating theater; a room thirty by twenty and thirty feet in height, marble floored and wainscoted, the whole well lighted by numerous windows. In the other are the surgeon's office and the *x*-ray and drug rooms. The third building is for private patients, and the fourth, the Zenana, contains the clinic and wards. A part of every hospital must be reserved as Zenana quarters for women in purdah, and the entire service therein must be female. The latrines or toilets are at either end of the buildings. They are simple and excellent. The urinal consists of a slanting stone or slate trough, and round or elliptical holes cut in the stone floor serve for toilets. On either side of the hole, fastened to or made upon the floor, are rings for the hands or slots for foot supports. Below is the cesspool or plumbing. Though rather startling at first, the cleanliness and absence of odor and the simplicity soon convert one to their use. Because of the laws of caste the culinary proposition presents difficulties we can scarcely conceive, and which only caste itself can accommodate. Members of various castes may not eat food prepared by or drink water drawn by members of other castes. Hindus have no use for Mohammedans, and vice versa, to some degree. As a consequence the patient is frequently accompanied by from three to eight relatives, who prepare his or her food and serve it. Because of the climate these attendants are able to do all this, as well as sleep, on the grounds about the hospital. Under each bed is a small glazed earthenware bowl which serves as bed pan and spit cup. During most of the year the bed clothing consists of two sheets. In the north some sort of blanket or comfortable is required at night. In the south, where the male suit is a turban and a loin cloth, or, as Kipling says,

"His clothing was nothing much behind
And something less than that before,"

the same suit is worn in bed. The turban often serves as a pocket for safekeeping of valuables; passing through a ward at night one fancies himself in a mummy chamber. One end of the covering sheet being caught under a heel, the other end passed over the forehead and under the head. The big toe now raises and pulls it taut, thus raising it from the body and face. A promenade between a double row of these stretched sheets partially outlining the mobile forms beneath is quite gruesome.

The wards and cloister-like porticos are stone paved and are daily flushed and brushed out by the sweeper with his bundle of brush, which, having no handle, he must manipulate from a squatting posture. The work, however, is thoroughly well done. The Hindu and Mohammedan must also have separate wards, and since the Hindu religion demands a daily bath, the Hindu wards are least odorous. The private rooms are really suites, consisting of bedroom, toilet and kitchen, for here again most patients prefer to have their food prepared by their own family or servants.

The common food is rice, rice twice a day and little else. Various sauces and curries are added and, if permitted, the better off have some variety of meat, vegetable, fruit and sweet; but so universal is the use of and fondness for rice that it occupies an important place in every menu. The traveler, likewise, soon finds a warm spot for it in his daily appetite. Rice and water as a satisfactory food eliminates much worry and difficulty. One frequently sees signs notifying the public that "patients may furnish their own food and have it cooked by the hospital." That food means rice. Because of the simple life, constipation is rare among the common people. There is always a roadside ditch, an aloe, or a prickly pear behind or beside which the native can squat; and since squatting is the common position of rest as well as for micturition or defecation, one can never know which the squatter is doing, and one never learns.

The daily work done by the Anglo-Indian surgeons, or rather English surgeons in India, is remarkable and rather belies the common notion of the enervating effect of the Indian climate. I have actually seen the following day's program carried out, and it is not exceptional: 8:30 to 10 A.M., private patients; 10 to 11, two court cases requiring a two-mile drive; 11 to 11:30, examination of police recruits (6), five assault cases, wounds examined and certificates written, signing of ten to twenty official papers; 11:30 to 3.30, thirty cataract operations, eight iridectomies, two litholopaxies, one ovarian cyst removed, one extirpation of cervical glands, besides the personal examination of 75 patients; 3:30, on, to court, two affidavits; 4, home to lunch; 4:30 to 6, private patients and tea; 6:30, three autopsies and a visit to the club; 8, dinner at home.

I may be permitted to add that Colonel Smith, from whose life I have given a day, has had time to perfect his cataract operation, publish it to the world, teach some two-score its performance, and maintain a civic usefulness, good health, and splendid ambition. His operation offers to the world the one satisfactory scientific and surgical procedure for removing the unripe as well as the ripe cataract entire. It offers relief from those years of impoverishing delay which cataract victims must suffer who wait for ripening of the lens. Though it is not widely accepted here, or in Europe, because of the difficulty of its performance because of lack of sufficient instruction and practice in it, or ultra conservatism, it is the operation of India and of all who have mastered it. It has been performed upwards of 28,000 times by Colonel Smith, and thousands of times more by his pupils, and such an experience with its wealth of result surely overcome any merely academic objection. It appeals to the populace of India, as it will in time to our people, and wherever Smith operates there gather the cataract patients from every quarter.

Throughout the East the hospitals are monuments to our profession. Everywhere the people revere the high ability, Christian manhood, and mighty labor of the men who have brought them the art and science of medicine and surgery. Not only in those great centers where now arise new and commodious buildings equipped to the level of modern acquisition in invention and discovery, resting indeed on the graves of those who but a few years ago in barest straits and almost impossible suffering, laid down their lives in the struggle with plague, pestilence, and famine. Not only there, but on the furtherest frontier, and in the wild central country, where none go unaccompanied by danger and small chance of return; in loneliness, and be it said proudly, without acclaim, may be found men of our world carrying healing, relief, sanitation, and brotherhood. Building hospitals, leper colonies, and schools, cleaning up the filth of ages, leaving as their memorial a greater hope and possibility for the generations unborn, and a generous meed of scientific values to us of the West.

Whatever the East may in time become or return, India with its sanitation and uplift, China with sanitation and humanity, Japan with sanitation and honesty, the Old World with its new and increasing respect for life, health and sacrifice, will owe much to those noble ones who went there with the gift of healing in their wings, the throb of brotherhood in their hearts.

PERSONAL EXPERIENCE WITH NEOSALVARSAN.*

By T. SCHAEPKENS VAN RIEMPST, M.D.,

NEW YORK.

The present status of neosalvarsan is very confusing, owing to the short time it has been in use and the contradictory reports of enthusiasts and skeptics. This short paper is simply a condensed narrative of personal cases, and the conclusions I have drawn are *ipso facto* purely personal.

The literature of recent years and even the newer textbooks on urology and syphilis have devoted much space to the technique of the injection, and the numerous and cumbersome apparatuses recommended. I shall mention only the absolutely necessary implements, viz., a boiling flask of a capacity of 300 c.c., a mixing bottle, a percolator with 5 or 6 feet of rubber tubing provided with two fenestræ, a coupler, and a few sharp, highly polished Chetwood or Schreiber needles. Furthermore, a tourniquet is necessary, and for this purpose we use a rubber catheter and an artery clamp. In the 120 intravenous injections given in the St. Luke's Hospital clinic, it was only once necessary to perform a venesection, and in over 300 injections given in the Polyclinic, only three times the vein was not found. In my own practice this happened twice. This makes a total of less than 2 per cent. It is a good plan, however, to be prepared to cut down on the vein, chiefly when we have to perform this little operation at the patient's home.

During the administration of neosalvarsan I have not observed a single disagreeable effect, except that occasionally the patients complain of an unpleasant taste in the mouth; some call it metallic, others compare it with the taste of ether. As this

*Read before the West Side Clinical Society, March 13, 1913.

occurred in at least one patient out of four or five, I have naturally tried to explain it. I venture the opinion that as soon as a little air is injected into the veins, the ether taste is present; but I am not sure that this is the real explanation. At this point it can be mentioned that the introduction of even a few cubic centimeters of air has no deleterious effect on the patient. The real after-effects of the drug made their appearance a few hours subsequent to the injection. A small number of patients (5 per cent.) had real discomfort, viz., obstinate vomiting, diarrhea, and headache, which lasted in some cases over twenty-four hours. A larger number (about 30 per cent.) complained of slight nausea, others of diarrhea, others of transitory headache; but in none of the 500 cases was there any really alarming after-effect, such as we have seen in the case of salvarsan. It is a curious phenomenon that some patients who received three or four injections would not feel a single after-effect following one or two injections, but would get a severe gastroenteritis after the third or fourth injection. Others on the contrary would get a severe reaction after the first injection and would be free from all disagreeable symptoms after the two following injections. This seems to exclude the theory that the cumulative effect of the arsenic in the first category of cases was the cause of the disturbances.

For the sake of brevity and convenience I have classified the cases treated with neosalvarsan in different groups. The first group comprises those patients who presented only primary sores without the appearance of secondaries. The diagnosis in evety case was corroborated by the laboratory test, viz., the dark-field illuminator, the Chinese ink method, and the Wassermann reaction. It is well to bring out at this point the very important fact on which Noguchi has laid great stress, namely, that often a primary chancre is not indurated and is not accompanied by satellite indurated glands. From our own experience we all know that patieuts have told us repeatedly that physicians had made a negative diagnosis of syphilis, based solely on the fact that the chancre was not indurated. It is well to bear in mind that every patient who has genital sores acquired in suspicious intercourse, be they chancroids or abrasions, may see a syphilitic chancre develop in due time. Therefore it is essential not to rely entirely on the clinical diagnosis, but to have recourse to the laboratory methods.

Group A.—This includes eleven patients who had primary sores without any secondaries. Three of these were chancres of the lip. One injection in ten cases prevented the appearance of secondaries and healed the lesion in about a week; one had a slight macular rash. This is a most important fact, principally when we have to deal with chancres of the face; one of these cases merits a little more than simple mention; this patient showed the strongest Wassermann reaction in a series of 120 cases which Dr. McFarland examined for this test. Secondaries, however, did not appear. Following the injection of neosalvarsan the hemolysis became gradually stronger, and 100 per cent. in the Madsen scale after the fifth injection.

Group B.—This group comprises the largest number of cases, but is the least interesting, because we see every day in our clinic the patients who come with or without primary lesions, but in the full secondary stage. But here again neosalvarsan shows its superiority over the old treatment in the rapidity with which the symptoms disappear, and those symptoms such as mouth and tongue lesions which we had to treat with caustic agents, often with very little result. This is adequately illustrated in the following case: A young married man was referred to me with a large secondarily infected chancre of the lip, general macular eruption, general adenitis, sores in mouth and tongue and pharynx, etc. His physician had given him twelve injections of bichloride of mercury and two injections of salicylate of mercury; the latter seemed to make no impression on the lesions, but made the patient salivate; one injection of neosalvarsan healed the lesions in a week; he received three more injections.

Group C.—In this group belong a number of cases in which either mercury, potassium iodide, or mixed treatment had been given for a longer or shorter period, and in which the symptoms, in spite of faithful treatment, did not subside or relapsed at irregular intervals. One case is particularly interesting, because it was one of the most intractable cases which came under my personal observation; this patient contracted syphilis in Germany twenty years ago; he was treated then with inunctions of mercury and remained under medical treatment for over two years. He came to me in February, 1908, with squamous syphilides of the palms of both hands. For 18 months I gave him regularly a weekly injection of salicylate of mercury (0.1 gram), and at different times gave potassium iodide in high doses. In spite of this treatment he had frequent relapses. He came to me again on June 1, 1912, with the same lesions; one injection of neosalvarsan cleared up the lesions, and until now he has been free from symptoms. Examples of this sort can be multiplied, but one will suffice.

Group D.—In this group mention will be made of several more or less interesting cases, most of them referrred to me by physicians of other departments. Three cases of osteoperiositis; all three of these patients had extensive areas of periostitis and thickening of the shaft of the tibia; they suffered intensely with nocturnal osteocopic pains; in every case an *x*-ray picture was taken and the Wassermann reaction performed; the latter was positive in every case. All pain disappeared in a few days and the thickening of the periosteum subsided gradually. Three cases of large gummata: The first was a young woman with conclusive syphilitic history and positive Wassermann reaction; she had large gummata of the leg, four in number; in spite of three injections, one of the lesions did not disappear after two months. The second case responded quickly after two injections. The third was a patient who gave a history of syphilitic infection twenty years previously; at his first visit to the clinic he presented a large gummatous ulceration of the left cheek, extending from the external angle of the eye to below the external angle of the mouth, and posteriorly as far as a point two centimeters in front of the ear. He was given two injections at an interval of a little over two weeks; the lesion was entirely healed after the third week; when the blood which was withdrawn immediately before the third injection was examined for the Wassermann test it was still doubtfully positive. Two cases of atheroma of the aorta: Both showed marked improvement in the subjective and the objective symptoms. Two cases of gumma of liver: The first was diagnosed dur-

ing a laparotomy for carcinoma of liver, the other was diagnosed as such by Dr. Miller; both gave positive Wassermann reactions and the palpable tumors and the concomitant symptoms disappeared after two injections. One case of early secondary pseudorheumatic arthritis: This lesion disappeared entirely in three days. One case of gummatous bursitis of knee: Mixed treatment and potassium iodide in large doses had no effect on the lesion; the Wassermann reaction remained positive, and gumma was unchanged. Two weeks after an injection of neosalvarsan the lesion was healed. One case of hereditary syphilis with positive Wasserman reaction: A boy of ten had frequent attacks of epilepsy; four injections of neosalvarsan failed to check the attacks in the least; it is possible, however, that this case is one of true epilepsy; a careful inquiry into the boy's family history reveals that his grandfather's brother was subject to epileptic fits. One case of multiple sclerosis. History of syphilis and positive Wassermann reaction. No result. I will say a few words about a group of patients who have been treated with either salvarsan or neosalvarsan within the last year, and who since the time of their injection did not take any specific treatment. The only criterion of a probable cure in these patients is the absolute freedom of symptoms during that whole period, and a negative Wassermann reaction done under favorable conditions; another proof of non-contagiousness at least, would be the inability of such a patient to infect his partner. I have only had one such case; a man who presented full clinical symptoms of syphilis and a positive Wassermann reaction. He received one injection of salvarsan and three of neosalvarsan, the last injection eight months ago. Since that time he did not take any specific treatment. For the last five months he has been living with a young woman whom he recently brought to me for examination; clinically both were free from symptoms, and both had a negative Wassermann reaction. Naturally it would be dangerous to draw conclusions from one such case. Twenty-five patients who had received salvarsan or neosalvarsan, and who were during a time varying from three months to twelve months without any treatment were submitted to the Wassermann test. Nine after two months were without symptoms and gave a negative Wassermann reaction. One after two months was without symptoms and gave a positive Wassermann reaction. The latter patient received four more injections; he never felt the slightest after-effect; the last time I saw him he was without symptoms, but he failed to return to the clinic for a Wassermann reaction. Five after three months were without symptoms and gave a negative Wassermann reaction. One after three months was without symptoms and gave a positive Wassermann reaction. Three after four months were without symptoms and gave a negative Wassermann reaction. One after six months was without symptoms and gave a negative Wassermann reaction. One after six months was without symptoms and gave a positive Wassermann reaction. Two after nine months were without symptoms and gave a negative Wassermann reaction. One after nine months returned with symptoms and gave a positive Wassermann reaction. This patient had received two salvarsan injections. One after twelve months was without symptoms and gave a negative Wassermann reaction.

Conclusions: (1) Neosalvarsan is preferable to salvarsan on account of its equal efficacy, its lesser toxicity and its easier mode of administration. (2) In an early diagnosis of syphilis, we can prevent the appearance of secondaries by the timely injection of neosalvarsan. (3) The dosage in children and infants should be based on body weight. If 0.9 gram is the average dose for an adult weighing 60 kilograms, 0.015 gram should be used for every kilogram of the child's weight. (4) Neosalvarsan is not a positive cure for syphilis, but is superior to mercury, potassium iodide, or mixed treatment, and should always be resorted to when lesions persist under such treatment. (5) The intravenous injection is preferable to the intramuscular injection, on account of the severe pain, the frequent abscess-formation, and the sloughing produced by the latter. (6) The introduction of a little air in the vein has no deleterious effect on the patient. (7) The intervals between the injections should never be shorter than a week.

152 West Seventy-third Street.

INDICANURIA, THE FECES, AND THE SULPHATES OF THE URINE.

By JOHN C. WARBRICK, M.A., M.S., M.D.,

CHICAGO.

In making an examination of the urine for the amount of indican present, especially with urines of a high specific gravity, some points that are of interest have been noted in more than one instance in connection therewith. The matter was gone about in the following way: First, a meal consisting chiefly of beefsteak was taken along with some coffee and bread; then afterwards an examination of the urine was made in each instance or after every meal and the results were tabulated from time to time. The amount of chlorides, phosphates, and sulphates were taken into consideration, especially the last, along with the specific gravity and the amount of indican.

The amount of feces passed was also taken into consideration, the color and odor being noted also at each examination as tending to have some part in the formation of indican in the urine and also of having some influence on the amount of sulphates, which were remarkably high on some occasions and also far beyond the amount of chlorides and phosphates. At times the odor of the feces was foul, which may have indicated a state of decomposition, while the small amount of chlorides found, especially in some instances, may have tended to indicate poisoning of the body tissues and a diminished change in the metabolic processes. At the first examination of the urine the specific gravity was high, being 1034, while the chlorides were at 30-465, the phosphates at 6-93, and the sulphates at 2-31, the amount of indican present not being recorded. At the next examination the specific gravity was slightly lower, at 1032, the amount of indican small, being as low as 3, while the feces were brownish in color.

In nearly all of the eleven examinations of the urine that were made the specific gravity was unusually high, and in most of them it was beyond the normal range of 1015-1025; while in only one instance was it within the normal range at 1024, the lowest recorded; while the highest specific gravity noted was 1040, a point that is not very often reached. In none of the reports was the amount of indican found to be high nor was the figure 7

reached at any of the examinations, while in two instances there was no indican found, although the feces had an aromatic odor. The sulphates had reached the remarkably high figure of 50-775, far beyond both the minimum and maximum daily amount and a point apparently not often recorded. From the large amount of sulphates recorded in two instances with the small amounts of chlorides each time it would seem almost as if the body metabolism had changed or that the tissue change had diminished and the sulphates had taken the place of the chlorides as an indication of this diminution. This may possibly be the explanation of the large amounts of sulphates in two instances with the small chloride index. This may go to show that where the normal metabolism of the body is disturbed from certain conditions the sulphates may increase and become much greater than the chlorides, whereas in health, when active tissue change is taking place, the chlorides are always much greater in amount than the sulphates and also much greater than the phosphates.

During these examinations there was some disturbance of metabolism, with inaction of the bowels and with a foul odor to the stools. The weight of the stool was nineteen ounces, which may have indicated a tendency to retention. Upon a free movement of the bowels at one time there was a peculiar agreeable and itchy feeling in the skin as if the body had been freed of something affecting it. This may have been due to the intestinal canal getting rid of some toxic products affecting the secretion of the skin or the nerves controlling it. The highest point the chlorides reached at any of the examinations was 30-465, while the lowest figure was 9-139.5.

The highest point the sulphates reached was at the unusual figure of 50-775 and the lowest figure was 1-155, thus making a wide range; one day the sulphates were at 50-775, then the next day they took a sudden drop to the low figure of 2-31 within the normal, but in neither of these instances was any indican present; however, in the next examination with a small amount of chlorides and a smaller amount of sulphates indican was still present, as indicated by the figure 7. Indican was found in eight of the urinary examinations, while twice it was absent under circumstances when its presence might have been expected. These circumstances were a high specific gravity and a large amount of sulphates. It will be noticed in one report, however, that with a specific gravity of 1028 and a large amount of sulphates at 40-620 the amount of indican tabulated was at 6.

Now why indican was present with the sulphates at 40 and absent when they were higher at 50 is not quite evident. At none of the examinations was the amount of indican high when all the conditions necessary for its formation seemed present to make it appear in the urine, while twice it was absent.

1. Color, yellowish red.
   Specific gravity, 1034.
   Chlorides, 39-465.
   Phosphates, 6-03.
   Sulphates, 2-31.
   Indican, not recorded.
2. Color, yellowish red.
   Specific gravity, 1032.
   Indican, 3.
   Feces, brownish color.
3. Color, reddish yellow.
   Specific gravity, 1024.
   Chlorides, 10-155.
   Phosphates, 2-31.
   Sulphates, 2-31.
   Indican, "6."
4. Color, yellowish red.
   Specific gravity, 1028.
   Chlorides, 25-387.5.
   Phosphates, 3-46.5.
   Sulphates, 2-31.
   Indican, "6."
5. Color, yellowish red.
   Specific gravity, 1030.
   Indican, 4.
   Bowels free.
   Yellow colored feces.
   An itchy feeling all over the skin.
6. Color, yellowish red.
   Specific gravity, 15-232.5.
   Phosphates, 2-31.
   Sulphates, 40-620.
   Indican, "6."
7. The same urine later in the day.
   Color, yellowish red.
   Specific gravity, 1028.
   Brown colored feces.
   Indican, "7."
8. Color, reddish yellow.
   Specific gravity, 1030.
   Chlorides, 7-108.5.
   Phosphates, 2-31.
   Sulphates, 3-46.5.
   Indican, "5."

This urine was examined after the patient had partaken of a meal of beefsteak and two cups of coffee, which represented a gain of 3pounds:

9. Color, yellowish red.
   Specific gravity, 1040.
   Reaction, alkaline.
   Chlorides, 20-310.
   Phosphates, 6-93.
   Sulphates, 50-775.
   Indican, 0.
   An aromatic odor.
   Feces, yellow.
10. Color, yellowish red.
    Specific gravity, 1036.
    Phosphates, acid.
    Chlorides, 20-310.
    Phosphates, 4-62.
    Sulphates, 2-31.
    Indican, 0.
    An aromatic odor.
    Feces, yellow.
11. Color, yellowish red.
    Specific gravity, 1028.
    Chlorides, 9-139.5.
    Phosphates, 3-46.5.
    Sulphates, 1-15.5.
    Bowels, clogged up.
    Feces, brownish color and partly liquid.
    Weight of stool, 19 ounces.
    Indican, 7.

306 East Forty-third Street.

TUBERCULOSIS IN THE UNITED STATES NAVY.

By ISAAC W. BREWER, M.D.,

Taughannock Falls, N. Y.

In previous papers the statistics of tuberculosis in the United States Army have been discussed. In those it was shown that while there has been a gradual decrease in the admission rate for pulmonary tuberculosis since 1900 the rate of decline has not been so great as the decline in the general admission rate. Or, in other words, the statistics for the army do not show the result of the campaign against tuberculosis.

In pursuing these statistics further I turned to the navy for further evidence. There we find that there is even less evidence of the benefits of the campaign against tuberculosis than in the army statistics.

In 1898 the admission rate was 4 per thousand; it rose to 5.5 in 1900, falling slightly during the following two years, only to rise to 6 per thousand in 1902 and 1903. Since then the rate has been irregular, generally above 4.5 per thousand. In 1910, the last year of record, it was 5 per thousand or one more than in 1898.

The following table shows the details of the admission rates per thousand for pulmonary tuberculosis:

Year.	Rate.	Year.	Rate.	Year.	Rate.
1898	4.0	1903	6.0	1908	5.8
1899	4.5	1904	6.0	1909	5.4
1900	5.5	1905	5.0	1910	5.0
1901	5.0	1906	4.5		
1902	4.0	1907	4.5		

For these statistics I am indebted to Surgeon-General Stokes of the Navy. In commenting on them in a private communication he says, "The great increase in the tuberculosis rate is probably largely due to the introduction of new, immature, and probably infected individuals." However, in plotting the strength of the Navy for the years under consideration and the admission rate we do not feel that such is the case. The curve of mean strength shows a continuous and almost uniform rise from the year 1899, with a flattening out during the years 1904, 1905, and 1906, and a marked increase to 1909, when the curve again flattens out. The curve of tuberculosis on the other hand shows a slight rise from 1899 to 1901, followed by a sharp fall in 1902 and a rapid rise in 1903. The curve is irregular to 1906 with a sharp rise in 1908 and a gradual fall since that date.

The statistics of the sickness in the Navy are not to be compared with any others, for they are subject to conditions which do not obtain in any other walks of life. That the results of the campaign against tuberculosis do not show in the Navy as soon as in the Army are not to be wondered at. The Navy serves in all portions of the globe where its personnel is submitted to conditions that are very trying to the human body. At best the ventilation of the ships is far from satisfactory, and when at anchor in a tropical port the decks are very hot and uncomfortable. It is also but natural that human beings after being long under confinement in cramped surroundings should "celebrate" their liberty, but whether the sailor is any less temperate than his brothers in civil life I doubt.

The death rates are not here considered because most of those who become sufferers from tuberculosis are discharged shortly after the diagnosis is made.

PNEUMONIA, IMMEDIATE AND CONTRIBUTING CAUSE OF DEATH; RATIONAL TREATMENT.

By W. C. K. BERLIN, M.D.,

DENVER, COLO.

Pneumonia, localized or otherwise, is characterized as an infection of a mixed type of more or less severity, depending upon the immunity or resistance of the person affected, with the pneumococcus probably predominating. That this type of infection is very toxic is evinced by the multiplicity of symptoms present, such as unusually high temperature except in the aged, gastrointestinal disturbances, urinary suppression with albumin, indicanuria, phosphaturia, and disturbances of the central nervous system. Heretofore heart exhaustion, due to toxemia and to obstruction of the circulation by a consolidation or gray hepatization of the lung, has been considered to be the immediate cause of death; yet we see cases proving fatal in which very little lung tissue is involved, thus seemingly contradicting this theory.

Having done a great deal of blood culture work, I have noted in all severe infections and bacteriemias a decided viscosity of the blood when drawn for diagnostic purposes. Blood drawn from pneumonia patients has been conspicuous in this respect. Following this condition further, I have visited a number of undertaking establishments and morgues, and have found that the blood is invariably clotted following death from pneumonia. Operators find it very difficult to draw blood from these subjects for the purpose of embalming, this difficulty being due to the clogging of their instruments by coagulated blood. With these findings in view, it would seem to be a fact that the more profound the infection and toxemia the more viscid the blood stream. The greater the viscocity of a fluid, the more power it takes to drive or pump it; hence we see a good reason for heart exhaustion and failure in this disease especially. The successful treatment of pneumonia bears a close relation to this condition, and the first effort should be directed to the prevention of this viscosity or so much so as to relieve the great strain on the heart until the regular cycle of this disease has passed, which is five to nine days, and until resolution has occurred either by crisis or lysis.

One of the early diagnostic features in pneumonia is the deficiency of chlorides in the urine. It would seem good logic to supply this evident insufficiency of chlorides in the blood and tissues. This is easily accomplished by giving intravenously moderately large amounts of isotonic saline solution, more or less frequently administered. This answers the double purpose of adding chlorides and of diluting the blood; it also stimulates the kidneys and furthermore facilitates the elimination of toxic material.

The usual treatment may be carried out. The bowels must be kept open as there is a great deal of tympanites always present, indicating the occurernce of fermentation and putrefaction, with the formation of indican and other toxic products that must be eliminated.

About two years ago I had the honor of introducing to the profession the safe administration of an iodine solution intravenously as a treatment for tuberculosis and different bronchial affections. Since that time I have noted during experiments on the blood, that this solution in small quantities added to a large amount of blood prevented coagulation and the mixture remained in a fluid condition for a month without hemolysis or destruction of the blood cells, as noted under the microscope. To this isotonic saline solution given intravenously I have added this iodine solution, to which were also added creosote and guaiacol for their anesthetic and germicidal action. The creosote acts strongly as a sedative to pain, relieves congestion, and greatly relieves dyspnea, making the patient more comfortable immediately. Although the number of patients so treated during the past two years has been too small to be conclusive, every case has recovered in spite of the fact that several had been given an absolutely bad prognosis by competent consultants.

MEDICAL RECORD.

THE SERODIAGNOSIS OF PREGNANCY.

THE attempt to make a diagnosis of a condition by means of an examination of the serum of the patient has introduced into pathological laboratories a large number of serodiagnostic methods within the past few years and a few of them have proven to be of the greatest help to the clinician. These methods can roughly be divided into four groups: 1. Methods which aim to demonstrate in the serum the presence of antibodies by means of direct recognition. The agglutination and precipitin tests are perhaps the best known in this group and their value has been quite accurately fixed. The demonstration of other antibodies, such as bacteriolysins, opsonins, etc., while of great interest to the immunologist, has so far benefited the clinician but little. 2. Methods which demonstrate the presence of antibodies in the blood-serum by means of complement-deviation tests. Among these are also some which have deservedly become well known and highly trusted. It is difficult to appreciate how much the Wassermann reaction, for instance, has contributed to the diagnosis of disease. 3. Methods in which the effort is made to demonstrate either the presence of abnormal substances in the serum, or the presence of normal substances in abnormal quantities. This group is naturally a large one since into it fall the earliest attempts to investigate the nature of the blood-serum in disease. For the same reason it contains numerous tests which have proven unreliable. At present the popular subject is the character of the serum in nephritis and a large amount of work has been done with results that have so far failed to prove of much value to the clinician. If the cobra venom reaction of Weil be included in this group it may be said to contain at least one test which is likely to prove valuable. 4. Methods in which the effort is made to demonstrate the presence or absence of specific ferments.

The latter is the youngest group of all and is based upon the work of Abderhalden and his school. Abderhalden claims that under normal conditions substances foreign to the blood do not enter into the general circulation, while those native to the blood do enter. In the process of digestion, for instance, the food is first disintegrated into dialysable products which are native to the blood and these after absorption constitute the "Bausteine" (building material) out of which the body is built and repaired. When substances foreign to the blood are introduced parenterally, the organism at once proceeds to elaborate ferments which are able to break down these substances into suitable "Bausteine." Several tests have been devised along these grounds, the best understood of which is the test for pregnancy. In Abderhalden's test for pregnancy the serum is tested for the presence of a ferment, which is able to digest placental tissue. A suitable mixture of serum and placental tissue is made and dialysed under certain conditions. The dialysate is then tested for the presence of peptone and amino acids.

During the past year there have been a number of contributions on this test and, as tried out with the serum of a number of pregnant women and the serum of healthy non-pregnant individuals as controls, it would seem at first to be a positive and conclusive test for the existence of pregnancy. Upon further thought, however, there are several important questions which remain unanswered. Is the test of any value in ectopic pregnancy when the ovum has been surrounded by blood clot for some days? Has it been proved conclusively that conditions other than pregnancy may not give rise to a positive result by this test? These questions remain still unanswered by these authoritative investigators.

In the MEDICAL RECORD of July 19, Gutman and Druskin report on a series of 357 tests made in 202 cases, and in the *Bulletin of the Lying-In Hospital*, 1913, ix, 68, Jellinghaus and Losee have published the results of 563 such tests and their conclusions. The difficulties encountered by the latter were numerous and interesting and will serve in a large measure to explain conflicting results which have been obtained by other workers with this method. Benefiting by their trouble they have been able to suggest certain precautions and improvements which they purpose to follow in their future work and which apparently will tend to improve their results. They prefer to consider the test one for the presence or absence of chorionic epithelium still capable of being washed into the general circulation rather than one for pregnancy or non-pregnancy, and as such it seems to be fairly reliable. It would not, however, always be useful in the diagnosis of an ectopic pregnancy.

The conclusions of Jellinghaus and Losee are interesting. They say that "if Abderhalden's claim is a fact the test may be useful in the following: (*a*) Diagnosing early pregnancy, especially in single women in whom an examination is refused. (*b*) Differentiating between uterine myomata and pregnancy. (*c*) In diagnosing chorio-epithelioma. (*d*) In diagnosing or excluding pregnancy in nursing women with amenorrhea. (*e*) In differentiating between pregnancy and other causes of amenorrhea (change of climate, tuberculosis, diabetes). (*f*) In differentiating between pregnancy and menopause in women with an enlarged uterus due to metritis. (*g*) That it opens a field for diagnosis in other diseases in which ferments are formed. (*h*) It offers a possible method of obtaining further information about the toxemias of pregnancy." Gutman and Druskin, in their conclusions,

dwell especially upon the applicability of the test to the diagnosis of many other diseases in which destruction of tissue is effected by means of specific ferments.

SURGICAL JUDGMENT.

Amid the multiplicity of details that occupy the attention of the professional man there is little opportunity for introspection. The demands of routine and the problems presented by concrete cases monopolize the entire intellectual activity of the physician, who rarely analyzes his own mind so as to detect the causes of its shortcomings or the origin of its failures. Nevertheless no more useful task can be conceived than that of taking an inventory of one's own capacities and limitations. This task is not an insuperable one and at any rate may serve to fill out the gaps in the day's work. At the present time, when the surgeon occupies the center of the stage, there is no more useful subject for reflection than that which is concerned with the mental equipment of him who has elected the most difficult of all arts, demanding for its efficient cultivation the highest resources of intellect and the keenest manual dexterity. A great deal has been said recently about the qualifications of the surgeon, and about the restriction of the practice of surgery to those medical men only who are fitted for it by special study and experience. Of particular and timely interest therefore is the discussion of surgical judgment.

Rarely has this subject been approached with such a lucid conception of the psychological elements involved as in the address delivered last December before the Southern Surgical and Gynecological Association by J. M. T. Finney and published in the *Bulletin of the Johns Hopkins Hospital*, July, 1913. Taking as his text the aphorism of Hippocrates, "Life is short, art is long, experience fallacious, judgment difficult," Finney presents a philosophical and at the same time practical analysis of the faculty of judgment so far as this enters into the exercise of the surgeon's art. The most fundamental and striking characteristic of judgment is the capacity for error, the recognition of which is essential in order that one may properly gauge its power and limitations. This liability to error is not restricted to any single mental act, but may occur in every one of the many psychical elements that are concerned in the elaboration of the finished judgment. Error may result not only from the imperfection of sense perceptions, and of the conceptual and reasoning faculties, but also from the imperfection of the so-called instruments of precision and of records. With this realization of the inherent weakness that exists all along the line of the mental forces, from the special senses to the graphic records of the mind's operations, one is in a position to diminish the liability to error and to train the faculty of judgment as an efficient pilot upon the sea of experience.

The first requirement in order to accomplish this object is an education broad and liberal. This is all the more necessary in the case of those who adopt surgery as a specialty, and who must bring to it the qualifications of insight, knowledge, and experience. Although a natural aptitude may enable some men to outstrip their colleagues in the practice of this art, nevertheless there is no royal road to surgical eminence. Finney points out that surgery is not alone an art, there being a wide distinction between operator and surgeon, and quotes the late John Homans of Boston who said: "Any fool can cut off a leg; it takes a surgeon to save one." To state the argument in a few words, the practice of surgery should not be undertaken by one who is not thoroughly grounded in its principles and technique, and who is not mentally equipped to deal wisely and promptly with its ever varying problems.

All of this appears too obvious to comment upon. Nevertheless every medical man can recall numerous instances of veritable tyros undertaking surgical operations of considerable magnitude or difficulty. Here as in other spheres of activity fools rush in where angels fear to tread. What are the causes of the apparent premium on mediocrity which prevails in the most difficult of all human arts? First of all may be mentioned the spectacular glamor of some of the work and the remunerative inducements which attract many of the younger but as yet inefficiently trained and equipped practitioners. Secondly, the multiplication of both public and private hospitals in cities and small towns has opened the door to the amateur surgeon. It is only too true, as Finney points out, that when a patient is operated upon in a hospital there is not the same feeling of individual responsibility upon the part of the surgeon as when a patient is operated upon in a private house. "Under the cover of the hospital, and in the more or less seclusion of its operating room, the would-be surgeon is tempted to do things that he would not dare to do under other circumstances." The modernized equipment and the regalia of the surgical amphitheater cover a multitude of surgical sins; the marble walls and shining brass only too frequently form a theatrical background for surgery that can be characterized more aptly as tragedy than as comedy.

In his analysis of judgment, Dr. Finney alludes to its important component, insight, which differs from knowledge in being more intimate and coherent, and in having a greater breadth, and a greater sureness of grasp. Good judgment demands honesty in the formulation of premises. It requires keen and accurate observation. It will not blindly follow precedent. The logical processes underlying judgment are not always readily apparent, and the aid of a constructive imagination is often indispensable. Sanity or common sense is a fundamental requisite of good judgment, the maintenance of which in the surgeon, as in every one else, demands a healthy body that is not driven beyond the limits of endurance. There are negative qualities besides that are associated with good judgment. Billroth said, "Years and experience bring in their train a certain degree of hesitancy." The good surgeon, always ready to operate promptly in the presence of an urgent condition, is nevertheless the one who will take time to study a patient sufficiently long to gain a comprehensive knowledge of his condition, realizing that "far-reaching possibilities

for good or for evil are lurking behind every surgical procedure."

A happy combination of truth and candor is perceived in the enumeration of the influences that lead to errors of judgment. These influences are errors of observation, the confusion of the relevant with the irrelevant, failure to comprehend the whole situation, "mental astigmatism," preconceived ideas, provincialism, prejudices, and human frailties. Is it altogether an unjust gibe of the comic weekly that the judgment of physicians is sometimes influenced by the character or personality of their patients? "We so often see that which we wish to see and fail to see that which we do not wish to see; we are prone to twist the facts to suit the theory, rather than the theory to suit the facts. Thus we deceive ourselves. Our reasoning is at times faulty. . . . Our emotions and our passions are given too free a rein. We are so prone to forget that we do not profit as we should by our mistakes. The sacrifice is often for us in vain."

Pasteurization of Milk at Low Temperatures.

In order to determine the best way of pasteurizing milk so as to destroy the pathogenic organisms and yet not give the milk a cooked flavor or lessen its nutritive value, the Department of Agriculture, through its Dairy Division, has been conducting a series of experiments, treating milk at different temperatures and for different lengths of time. According to the report on these experiments in Bulletin 166 of the Bureau of Animal Industry, when milk is pasteurized at 145° F. for thirty minutes the chemical changes are so slight that the digestibility of the proteins can hardly be affected. Of great interest also is the announcement by the bureau that when low temperatures are used lactic acid organisms constitute a majority of bacteria that survive, whereas the bacteria which survive pasteurization at high temperatures are largely of the putrefactive kinds. Pasteurization at low temperatures is also commercially economical, as it takes about 23½ per cent. less heat to raise milk to the temperature of 145° F. than to a temperature of 165° F., and it also requires 23½ per cent. more refrigeration to cool milk to the shipping point when it is pasteurized at the higher temperature than at 145°. The department, therefore, recommends that pasteurization should be effected by heating the milk to about 145° F. and holding at that temperature for 30 minutes.

The British Journal of Surgery.

It is a curious fact that Great Britain, the home of Lister, who made modern surgery possible, should alone of the great countries of the world have hitherto had among its periodicals no distinctively surgical journal. Readers who would learn at first hand of the work of such men as Arbuthnot Lane, Moynihan, Watson Cheyne, Macewen, Morris, and a score of other surgeons of the first rank in the United Kingdom were forced to turn to the pages of the great English weeklies, the Proceedings of the Royal Society of Medicine, or even to the American surgical journals, for there was no special periodical where the record of their work would be found. To supply this obvious lack there has been established a journal with the above title, the first number of which (July, 1913) has just been received. The journal is of the size and general style of the *Quarterly Journal of Medicine*, and is issued under the editorial direction of a committee of twenty-nine among the best-known British surgeons, the chairman being Sir Berkeley Moynihan of Leeds, the secretary Mr. E. W. Hey Groves of Bristol. This first issue presents a very attractive appearance, being illustrated with about seventy handsome colored and half-tone pictures. The frontispiece is a portrait of Lord Lister and is accompanied by a brief biographical sketch. The make-up of the journal consists of Original Communications, Critical Reviews, Visits to Surgical Clinics at Home and Abroad, Instructive Mistakes (related anonymously), Short Notices of Rare or Obscure Cases, New Instruments and Appliances, and Reviews and Notices of Books. If succeeding issues maintain the standard of readableness and good looks set by this initial number, British surgery will no longer have reason to complain of not being adequately represented in the periodical literature of that nation.

News of the Week.

The Seventeenth International Medical Congress met in London on Wednesday of this week. The inaugural session, held in Albert Hall, was opened by Prince Arthur of Connaught representing King George. The address of welcome was delivered by Sir Edward Grey who said the world was living in expectation that at any time a corner of the veil might be lifted yet higher by investigators, laying bare more of the mysteries of medical science. Sir Thomas Barlow, President of the Congress, followed with an address in which he spoke of the rapid progress being made in sanitation and the healing art, paying a tribute to the triumphs of American medicine in the sanitation of Cuba, Porto Rico, Panama, and the Philippines, and in its war on the hook worm and other plagues of mankind. Then the delegates from foreign countries made the usual addresses, being headed by Dr. W. H. Thayer for the United States.

In the afternoon the Address in Medicine was delivered by Professor Chauffard of Paris, who took as his title, "Prognosis in Its Relation to Evolution, and Its Present Limitations."

The section work began Wednesday afternoon. A resolution was introduced in the Section on Physiology by Sir E. A. Schäfer to the effect that it was the sense of the Congress that animal experimentation had shown itself to be of great service in the past and would be an essential aid to future medical progress. It was carried unanimously. The registered members of the Congress number about 8,000, the largest attendance from any country after Great Britain being from the United States.

There was some apprehension that the proceedings of the opening session might be marked by a suffragette demonstration, but the militants contented themselves with stationing near the entrance of Albert Hall "sandwich" women bearing placards with the question in large letters, "What do the doctors think of woman torture?"

Americans in the Royal College of Surgeons.—On July 31 the Royal College of Surgeons of London elected to honorary fellowship, among others, the following Americans: Dr. Harvey Cushing, of

Boston, Dr. J. B. Murphy of Chicago, Dr. William J. Mayo of Rochester, Minn., and Dr. George W. Crile of Cleveland.

City Death Rate.—For the week ending July 26 the death rate in New York City was 12.13 per 1,000, representing a total of 1,249 deaths, as compared to a rate of 13.26 and a total of 1,315 deaths during the corresponding week of 1912. Of infants under one year of age there were 298 deaths during the week, a decrease of 52, the total number of such deaths so far this year being 268 less than the number to the same date of last year. The general death rate for the first thirty weeks of 1913 was 14.67 per 1,000, while for the same period of 1912 it was 14.83.

Auto Ambulance Crash.—In a collision between a trolley car and an auto ambulance from St. Vincent's Hospital, Borough of Richmond, New York, on Richmond Terrace, New Brighton, the ambulance surgeon, Dr. Charles Brush, sustained a fracture of the right arm and other injuries, and the chauffeur also was seriously hurt.

Cholera in Hungary.—In accordance with the international agreement, the Hungarian Minister of the Interior has notified all the other governments of the occurrence of a case of cholera at Temes-Sziget in Hungary.

Quinine Cost to Soar.—An agreement between the European makers of quinine and the Java growers of the cinchona tree is likely to result in an increase in the cost of the drug. By the terms of the agreement the manufacturers are required to buy from the producers cinchona bark equivalent to about 1,000,000 pounds of quinine a year at a fixed price. Practically all of the bark used by the quinine manufacturers of Europe is produced in Java, whence it is shipped to Amsterdam and sold at public auction.

Dr. Frank P. Norbury, Alienist to the Board of Administration of Illinois, has resigned this appointment, to take effect October 1, 1913. Dr. Norbury will enter upon consulting practice at Springfield, Illinois.

Dr. Arthur A. Howard has been appointed physician-in-chief at the Children's Hospital, Boston, succeeding Dr. William P. Lucas, who has become professor of pediatrics in the Medical Department of the University of California.

Dr. Karl F. Meyer, a member of the veterinary faculty of the University of Pennsylvania, and director of the laboratories of the State Live-stock Sanitary Board, has resigned, to become professor of bacteriology and protozoology in the University of California. Dr. Meyer came to the University from the Transvaal, where he was an English Government pathologist in the Department of Agriculture. He will be succeeded by Dr. James B. Hardenberg, who was graduated from the Veterinary School of the University in 1911 and since then has been an assistant to Dr. Meyer.

Quiet for Sick.—Sheriff Harburger of New York, at the suggestion of Mrs. Rice, has recommended the appointment of special deputy sheriffs in all the hospitals of New York to aid in the enforcement of the laws prohibiting noise in the vicinity of hospitals.

Street Traffic Fatalities.—During the month of July, just passed, there were forty-one persons killed by vehicular traffic on the streets of New York City, of whom twenty-five were children under sixteen years of age. Automobiles killed twenty-six; wagons, eight, and trolley cars, seven.

Research in Tuberculosis.—In connection with the Bennett Medical College, the medical department of Loyola University, Chicago, there has recently been established a research laboratory for the purpose of testing "the efficiency of any remedy, preparation, or treatment, designed, compounded, or produced for the cure of pulmonary tuberculosis." The laboratory, which was made possible by a generous gift from Mr. William Lorimer, has on its staff the following members of the faculty of the medical school: Director, Dr. Maximilian Herzog, professor of pathology; Collaborator, Dr. W. A. Newman Dorland, professor of obstetrics; and Diagnostician, Dr. Oscar B. Funkhouser, professor of medicine. A monthly bulletin will be issued by the laboratory, in which the progress of the work will be described.

Gifts to Charities.—By the will of the late Elizabeth L. Lewis the Presbyterian Hospital of Philadelphia receives a bequest of $100,000.

By the will of the late Mrs. Anna Moore of this city provision is made for the establishment, in some place in New Jersey to be selected, of a home for convalescents to be known as the James Amory Moore Memorial Home. The amount of the gift so made is estimated at over one million dollars.

The Rhode Island Hospital, Providence, receives a bequest of $200,000 by the will of the late Mrs. Jane F. Brown of that city, and $25,000 is left to St. Joseph's Hospital, and $10,000 each to St. Elizabeth's Home and the Bethany Home.

By the will of the late Miss Elizabeth L. Lewis of Philadelphia the sum of $105,000 is bequeathed to the Presbyterian Hospital of that city. Of this sum $50,000 is to be used for the erection of a new building on the present hospital grounds or at the convalescent home at Devon, as a memorial to the parents of the testator, Samuel A. and Sarah Lewis; and the income from $50,000 is to be used for maintenance. A further sum of $5,000 is for the endowment of a free bed in memory of Sarah S. L. Brodhead.

Obituary Notes.—Dr. Elza V. Coldren of Topeka, Kan., a graduate of the College of Physicians and Surgeons of Keokuk, Ia., in 1864, a veteran of the Civil War, and a member of the American Medical Association and the Kansas State and Shawnee County Medical Societies, died at his home after a short illness, on July 17, aged 72 years.

Dr. James Bernard Shannon, Jr., of Danielson, Conn., a graduate of the College of Physicians and Surgeons, New York, in 1896, and a member of Connecticut State and Windham County Medical Societies, died at the home of his brother in Falls Village, after a long illness, on July 15, aged 42 years.

Dr. Phil Porter of Springport, Mich., a graduate of the Long Island College Hospital, Brooklyn, in 1875, died in Chicago, after a short illness, on July 14, aged 61 years.

Dr. Andrew Liddle Fulton of Kansas City, Mo., a graduate of the Bellevue Hospital Medical College, New York, in 1870, and a member of the Missouri State and Jackson County Medical Societies, died at his home on July 15, aged 70 years.

Dr. Harry Stillman Wilcox Spencer of Kankakee, Ill., a graduate of Rush Medical College, Chicago, in 1908, and a member of the Illinois State and Kankakee County Medical Societies, be-

ing a former secretary of the latter, was drowned while fishing in the Kankakee River, on July 17, aged 34 years.

Dr. George R. Westbrook of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1878, and a member of the New York State and Kings County Medical Societies and the Brooklyn Pathological Society, died suddenly, from heart disease, at his summer home near Benson, N. Y., on July 24, aged 65 years.

Dr. Gregory Doyle of Syracuse, N. Y., a graduate of the New York University Medical College in 1865, president of the United States Board of Pension Examiners in Syracuse from 1885 to 1890, surgeon general and major in the National Guard of the State of New York from 1872 to 1890, and consulting surgeon to St. Vincent de Paul's Asylum, died at his home on July 23, aged 73 years.

Dr. John S. Warren, formerly of New York, a graduate of Dartmouth College, Hanover, N. H., in 1862, and of the Jefferson Medical College, Philadelphia, in 1866, a veteran of the Civil War, and a member of the New York Academy of Medicine, the New York State and County Medical Societies, having served as treasurer of the last for fifteen years, the Society for the Relief of Widows and Orphans, and the Physicians' Mutual Aid Association, died at his home in Atlantic City, N. J., on July 18, aged 72 years.

Dr. Jerald Waddell of Montreal, Ont., a graduate of McGill University, Medical Department, in 1907, and a member of the laboratory staff of the Montreal General Hospital, died at the home of his father in Chatham, Ont., on July 13.

Dr. Roderick McLennan of Quincy, Mass., a graduate of Trinity Medical College, Toronto, Ont., in 1887, attending physician to the Quincy City Hospital, and a member of the American Medical Association and the Massachusetts State and Norfolk County Medical Societies, died at his home, after several weeks' illness, on July 23, aged 53 years.

Dr. Ransom Newell Murray of Flint, Mich., a graduate of the Jefferson Medical College, Philadelphia, in 1866, a member of the American Medical Association and the Michigan State and Genesee County Medical Societies, and until recently medical director of the Michigan School for the Deaf, died at the home of his daughter, in Mendon, Mich., on July 19, aged 83 years.

Dr. Arthur L. Wright of Carroll, Ia., a graduate of the Rush Medical College, Chicago, in 1874, and a member of the American Medical Association, of which he was a former vice-president, the Western Surgical Association, and the Iowa State and Carroll County Medical Societies, died in the American Hospital, Paris, after undergoing an operation for intestinal obstruction, on July 19, aged 62 years. Dr. Wright had gone abroad as one of the American delegates to the International Medical Congress in London.

Dr. William H. Evans of Sedalia, Mo., a graduate of the Bellevue Hospital Medical College, New York, in 1867, a veteran of the Civil War, a member of the American Medical Association, a member and former president of the Missouri State Medical Society, and a member of the Pettis County Medical Society, died in a sanatorium at Kansas City on July 20, aged 73 years.

Dr. Edward Francis Dowd of Waltham, Mass., a graduate of the Harvard Medical School, Boston, in 1898, died at his home from pneumonia, after a brief illness, on July 26, aged 38 years.

Dr. Simon P. Wise of Millersburg, Ohio, a graduate of the College of Physicians and Surgeons, New York, in 1871, and a member of the Ohio State and Holmes County Medical Societies, died suddenly, from neuralgia of the heart, on July 15, aged 65 years.

Dr. James D. Van Derveer of North Branch, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1866, died at his home, on July 30, after a brief illness, aged 75 years.

Dr. Bernard A. Duhigg of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1894, and a member of the Brooklyn Medical Society, died recently at his summer home at St. James, L. I.

Correspondence.

FREE PERSPIRATION A PATHOGNOMIC SIGN OF MEASLES.

To the Editor of the Medical Record:

Sir:—In connection with the instructive paper on the differential diagnosis between scarlet fever, measles and German measles by Dr. S. D. Hubbard, allow me to add another clinical sign which often proves very helpful in this direction. This symptom consists in *free perspiration* during the entire course of German measles, whereas the skin is invariably dry and more or less hot in scarlatina and morbilli. The free perspiration is due to the fact that in German measles not only are the lymphatic glands (including the spleen—which, by the way, is often greatly enlarged) involved, but the sudoriferous glands as well. I noted this symptom some eighteen years ago during the prevalence of the aforementioned three affections simultaneously at the H. Sh. G. S. Orphan Asylum and have since had many occasions to confirm the correctness of that observation.

Herman B. Sheffield, M.D.

New York.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

BRITISH MEDICAL MEETING—INSURANCE, APPROVED SOCIETIES AND MALINGERING—MEDICO-PSYCHOLOGICAL MEETING—FORCIBLE FEEDING—THE NEW POET LAUREATE—OBITUARY.

London, July 18, 1912.

The annual meeting of the British Medical Association will occupy next week. In fact it may be said to begin to-day, for officials and representatives are at work on questions important to the proceedings but scarcely interesting to you. The practical medical work opens on Tuesday next. Meantime the executives have issued a report in which several schemes of reform which have been put forward are criticised. These schemes result from the dissatisfaction that exists with the constitution, and specially on account of the failure to cope with the Government as to the Insurance Act. The constitution of the association is complex, and what with branches, decisions, groups, representatives, or delegates, busy practitioners are little disposed to study it. Hence it is that power has always tended to fall into the hands of the executive council, and what are spoken of as "vested interests" in the seats of that body occasion much dissatisfaction. The present council has considered the schemes of reform put forward as above stated and proposes

an extensive increase of its own powers. To accomplish this they make the drastic suggestion to dissolve the present society and form a new limited company to take over the property and hold it in trust for the purposes for which it has been raised. The past history of the association, or rather of its former government, has not been such as to secure confidence in its wisdom or justice. In fact for many years its action was proverbial as unworthy of the profession, and it is no easy matter for anybody to escape the condemnation its predecessors may have earned. A second report has also been made public and will have to be discussed. It comes from the state sickness insurance committee, and recommends the formation of a special fund for the organization and protection of the profession and its members; the control and administration of this fund to be vested in the council as trustees with power to delegate their duties to committees if they deem it desirable. Medical defense, sickness, and accidental insurance, endowments and pensions would be met by this fund, which would be raised by a voluntary subscription of sufficient amount. It is obvious that the council desires to organize the whole profession and to be the ruling executive; but from all one hears at present general support will not be forthcoming. This, however, and other medico-political matters will be brought forward at Brighton where the annual meeting is being held this year.

The approved societies are already finding out that the sickness expectation on which they based agreements to work the Insurance Act is being enormously exceeded. One cause is malingering. When the measure was being forced through Parliament this was foreseen by many as likely to occur, but the Government refused to listen to this or any suggestion. The societies (*i.e.* the large clubs which had always taken precautions) were anxious to undertake the administration of the act and accepted the Chancellor's estimates. The results are causing them disappointment and grave anxiety. It was estimated that sickness benefit would be 1½ per cent. per annum. In one society 2.21 per cent. of male members and 3.41 per cent. of females are on the funds without reckoning disablement benefit that will come on later. In the winter there is always a higher ratio than in other seasons and the societies did not cry out at that. But the last two months they have been alarmed—especially at the increased amount of sickness among females. A proportion of this is attributed to the maternity benefit, and most unexpectedly certificates of "debility" and similar troubles have come in for two or three months preceding delivery, thus greatly increasing the maternity benefit in a way that Parliament is believed not to have intended. The societies cannot expel members as they could when they were only voluntary clubs, and the systematic visitation they carried out by their fellow workers proved a preventive of fraud. Of course many people are blaming the doctors for giving certificates on insufficient grounds. It is said that liability and other slight causes of illness are given. The act requires the person to be *totally* incapable of work. This is very different from being unable to continue factory employment. A woman engaged in such and drawing full pay may be unable to continue that satisfactorily and yet she may not be "totally incapable" of any kind of work. There is an amending bill before Parliament which has been called a "tinkering" one. It is meant to deal with this among other questions which are mostly due to the way in which the scheme was hustled through and all amendments refused consideration. Now within a year they have to be considered and are expected to cost an additional sum of £1,000,000 a year. Mr. Masterman, financial secretary, gave currency to the statement that the doctors endeavored to pick out the "best lives," gave certificates carelessly, and when challenged said the Manchester doctors had themselves set up a committee to prevent it. He has thereby drawn upon himself the scornful retort that he either spoke in ignorance or ignored the facts. If he knows them, Dr. Helme tells him he is unfitted for his position, and Sir James Barr's statement that the act is "hollow fraud" is quite true. Dr. Waltenberg declared that if Mr. Masterman were not sheltered by the privileges of the House of Commons he would not have hesitated to challenge him to prove or apologize for his misstatements.

At the seventy-second annual meeting of the Medico-Psychological Association Dr. Newington, for twenty years treasurer, and president in 1889, was presented with his portrait in oils by Mr. Ouless, which was placed in the Royal Academy. At the dinner of the association Sir J. Crichton-Browne made a much-needed statement about forcible feeding, which has been spoken of by politicians as "torture," and I regret to say also by surgeons who ought to know better. Sir James said the members of that association were entitled to speak. If it is called an operation, all performed it; he had done it himself hundreds of times and seen it done thousands, and was sure it had saved tens of thousands of lives. He mentioned a man who had been so fed for fourteen years.

Dr. Robert Bridges has been appointed Poet Laureate. Many people were inclined to think the office would be discontinued and some profess to be disappointed that it is otherwise determined. The new Laureate was educated for and practised the profession. He graduated M.B. Oxford in 1874, became assistant physician at the Great Northern and the Children's Hospitals, and held some other appointments. He retired in 1882 to devote himself to poetry, in which he had previously attained some distinction. In 1876 he issued privately "The Growth of Love," in sixty-nine sonnets. Soon after leaving the profession "Prometheus" appeared (privately printed also in 1883). His "Shorter Poems" (1890) are considered by many his best and are certainly the most popular. The collected edition of his works extends to eight volumes. Dr. Bridges is not only a poet. He has written much prose and is a classical scholar of no slight eminence. Indeed some think his classical knowledge and predilections tend to injure his poetry and make him the delight of the few classicists rather than the singer of the English people. But your literary organs will analyze his works for you. Here it is only as a medical man that I speak of him, after the example of the Royal College of Physicians which elected him a Fellow in 1900.

Last evening your Ambassador, Dr. W. H. Page, was entertained at the Anglo-Saxon Club here, and in the course of an eloquent speech said that a wealthy American gentleman had given $100,000,000, the interest of which he wished devoted to the eradication of disease by an international health commission.

Dr. F. Gotch, F.R.S., professor of physiology at Oxford, has died after a prolonged illness, to the great regret of a large circle of scientists and medical men. He was the son of the Rev. D. Gotch, one of the revisers of the Old Testament, a theologian and scholar of great eminence. Soon after graduation and taking M.R.C.S. he was appointed assistant to Burdon-Sanderson in the Waynflete Chair of Physiology and succeeded to the professorship when Sanderson took that of medicine. He contributed much to the Royal Society's *Proceedings* and the *Journal of Physiology*. He was M.A. Oxon. and D.Sc. Oxon. and Liverpool, LL.D. St. Andrews, and received many other honorary distinctions. His Croonian lecture on the mammalian nervous system was delivered in 1891 before the Royal Society, of which the next year he was made a Fellow, and soon after a Councillor.

OUR CANADIAN LETTER.

(From Our Regular Correspondent.)

MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

It would be impossible in a limited space to deal with the program in detail or to discuss many of the papers read in the various sections with the attention that their importance deserves. However, there were some features of outstanding interest. For instance, an especially instructive paper was read in the section of general medicine by Dr. Hugh McGougan on "Acute Bronchitis and Pneumonia in Infancy and Childhood." Referring to the management of a child with acute bronchitis McGougan pointed out that early and free purgation not only lessens the toxemia, but also provides for freedom of the respiratory movements. Calomel in divided doses followed in a few hours by castor oil or a saline is effectual. For its diaphoretic and diuretic action liquor ammon. acetat. combined with an alkaline expectorant such as citrate of potassium in doses of 1 to 2 grains every three hours to a child of one year gives good results. Of the stimulating expectorants ipecacs or perhaps antimony in the form of the wine are of value during the acute stages, senega and squill being indicated for the later stage. The diffusible stimulants spirit. ammon. aromat. and spirit. chloroform. are of value in counteracting the depression of the disease. Opium, while certainly not contraindicated, requires care and watchfulness on the part of the prescriber. Where the dyspnea is producing stupor or even dullness opium in any form is contraindicated. It is best exhibited in the form of paregoric, or of Dover's powder. Codeine in the form of the syrup, also heroin, have their advocates. As to food, the child should be nourished mostly on milk, given in measured quantity and at regular intervals of two or three hours, preferably diluted with water or lime water. Between these times the child should be encouraged to drink freely of water. There should be no objection to a variation of diet. Care, however, must be taken to prevent a distention of the stomach or the intestine, thus hampering the respiration. Should tympanites develop it should be treated immediately by turpentine enemata and stupes and the use of tonic laxatives. Stimulants should be given early in severe cases to counteract the depression.

When the symptoms of bronchopneumonia predominate the treatment will vary according to the amount of the bronchitis, the height of the fever, and the general condition of the patient.

Dr. Goldwin Howland, physician to the Outdoor Department for Nervous Diseases at Toronto General Hospital, read a paper on the Functional Disorders of the Nervous System, Hysteria and Neurasthenia, Antiquated Diagnoses. Howland criticised the common use of the terms neurasthenia and hysteria as inaccurate. According to Howland, with regard to neurasthenia and hysteria, we find that science has not followed a rational method of advance and instead of gradually reaching the true terminology and dividing these diseases according to their causes, the tendency has been to widen the enormous field which these terms include, either by separating them from other classes, such as psychasthenia based on a similar collection of general symptoms, or by subdividing the functional diseases and forming classes such as cerebroasthenia and somatasthenia, sexual neurasthenia, etc. Such subdivisions are not the result of an attempt to make cause the basis for the separation, for it will be realized at once that sexual neurasthenia is by no means caused by sexual conditions, nor gastric neurasthenia by stomach malfunctioning. These subdivisions are simply the extension of the plan of collection, generalizing into disease and then separating such into groups arranged according to disturbances of similar functions. Howland draws attention to the fact that Sigismund Freud has evidently tried to avoid this unsatisfactory method. He has isolated anxiety neuroses, masturbation neurasthenia from the group, truly a division based on cause, but unfortunately one whose value is limited, as he has obtained such a small number of groups based on cause for such an important disease as neurasthenia. With hysteria the length of its scientific life has evidently placed the disease beyond any attempt at a similar recovery. Howland urges that the functional disturbances of the nervous system must be separated into diseases classed according to cause, not on the present basis of calling a collection of symptoms a disease. So that in advising the relegation of neurasthenia and hysteria into the field of obscurity, he does so, in the first place because the natural method of advance is the collection of symptoms and their separation according to specialized function. Secondly, the determination to see if the general nervous function is at fault, such general conditions as irritability are here referred to. Thirdly, when possible the association of such functional derangements in specialized centers with pathological conditions, be they gross or minute, and finally and always most important the discovery of the cause. Howland also criticises the classification of insanity. He claims that such disorders as alcoholism, toxic conditions which affect the brain and spinal cord, epilepsy and epileptic insanity, and even general paralysis and tabes are practically in the same class as the functional nervous disorders. They are nearly all divided according to the groups of symptoms—manic depressive insanity, dementia præcox—and there is no true scientific care; all are treated by symptoms and there will be no success until the causes are differentiated. Another reason for laying aside the diagnosis of neurasthenia and hysteria is that one is turned from a great opportunity for studying and differentiating the diverse functions of the nervous system. Again, in the teaching of students by the present method we find that they begin to look upon neurasthenia and hysteria as a token for all that is uninteresting in medicine, as a

type of a case which has nothing tangible behind it. But if you commence teaching disturbance of function you give the men some definite problem to work out, and if you show them the necessity for arriving at a cause you have men keen and interested in the various cases they had previously scoffed at. Yet another reason for urging the change is important—it is to avoid mistakes in diagnosis. According to Howland, the worst mistakes that he has come across have been always in diagnosing as neurasthenia and hysteria diseases that were of a most serious nature, and the cause for this has been that where there is a group of symptoms such as neurasthenia covers, this group frequently precedes the onset of more advanced signs of other diseases and the physician accepts neurasthenia as a diagnosis to save him the attempt to find a cause. In these cases the most terrible mistakes occur. The fifth reason is that in using the terms neurasthenia and hysteria the medical man regards them as if they were definite diseases and normal for a definite type of individual. Sixth, in these diseases the typical functional disturbances which they include are not necessarily present in the same individual, and lastly, the individual you at one time termed hysterical may at another give symptoms typical of neurasthenia. Summing up, Howland makes an urgent plea that the terms neurasthenia and hysteria should not be used as diagnostic conclusions, but should be entirely omitted, and submitted the contention that the time has come for reviving the study of the general functional disturbances of the nervous system, using the vast material which has been acquired; we should also endeavor to make more definite research into the specific differences of function belonging to nerve cell groups in different parts of the nervous system and that there should be further advance made in associating these functional disturbances with chemical and physical changes in the nerve cells, and finally and most important of all we should decide to classify our functional disturbances only according to cause.

In the same section Dr. G. S. Glassco of Hamilton, Ont., read a paper on the evolution of the neurotic and the application of psychoanalysis in the treatment of the same. In the course of an able and interesting paper Glassco endeavors to explain what Freud really means by the term sexual. He says: "Many have strongly objected to Freud's theory, principally on account of the term 'sexual,' translating it for themselves to mean sexual in the narrowest sense, in fact, pertaining to the consummation of the sexual act. According to Glassco neither Freud nor Jung, who has elaborated Freud's theory, intended to convey any such restricted meaning to this term. Rather does it embrace life and love and creation, indeed, the whole diffused tendency to seek expression, starting with mother love and graduating to the power to not only create life but to be capable of any creative work. Jung claims that the first instinct of the child is not sexual but nutritional, and Freud, while conceding this point, claims that in so far as nutrition is necessary to maintain life, it is indirectly concerned with the creation of life and therefore belongs to the sexual field. So that if this interpretation is accepted many of he objections to Freud's theory will be done away with.

Dr. C. S. McVicar of Toronto read a paper treating of some psychiatric problems as they affect the general practitioner and came to the following conclusions: 1. That the incidence of cases showing a greater or less degree of mental illness is larger than we heretofore supposed. 2. That we are not fully equipped to deal with such cases. 3. That as a result of our lack of equipment cases are allowed to progress where arrest or care might be looked for. 4. That the best means for physicians to combat the evil of irregular practitioners is to equip themselves more thoroughly to deal with this class of cases, because they are cases upon which quacks fatten. 5. That the remedy lies in more searching investigations and more efficient education. 6. That a more efficient education would result in (a) a great many cases being arrested before there is any need to send them to an insane asylum, (b) a great many cases now in asylums could be treated at home. 7. That the economic value of the question demands the fullest consideration by the State. As said before, the meeting on the whole was a success, although the attendance was hardly as satisfactory as had been hoped. The quality of the papers throughout the meeting was excellent and the social aspect of the meeting was bright and cheery, due mainly to the efforts of the local profession and the inhabitants of London in general to offer hospitality unstintedly.

The executive council of the association was selected as follows: Dr. F. P. Drake, London; Dr. MacKid, Edmonton; Dr. Primrose, Toronto; Dr. Small, Ottawa; Dr. Adami, Montreal; Dr. Reeve, Forest; Dr. Halpemey, Winnipeg; Dr. McKechnie, Vancouver; Dr. Brett, Banff; Dr. McNeil, St. Johns; Dr. Mader, Halifax; Dr. Park and Dr. Whitelaw, Edmonton, and Dr. F. U. G. Starr, Toronto.

St. John, New Brunswick, was selected as the next place of meeting, and Dr. Murray Maclaren of that city as the next president.

An interesting feature of the meeting was the honoring of Sir James Grant of Ottawa, who is considerably more than ninety years of age, by making him an honorary member of the association for life in view of distinguished service in the past. It may be mentioned that out of the forty-six meetings which the association has held he has missed only three.

Progress of Medical Science.

Boston Medical and Surgical Journal.

July 24, 1913.

1. Contribution from the Psychopathic Hospital, Boston, Massachusetts: Introductory Note. E. E. Southard.
2. The Wassermann Reaction in Its Application to Medicine. W. P. Lucas.
3. The Obstetrical Problem of the Poor. A. K. Paine.
4. The End Results of Excision of the Knee for Tuberculosis with and without the Use of Bone Plates. R. B. Osgood.

1. The Psychopathic Hospital.—E. E. Southard points out that the contributions of a psychopathic hospital like the new Boston institution are likely to emanate from the laboratory and to be of somatic trend. Their source will, however, be the patients themselves, since many psychiatric problems (*e.g.*, those of speech) are hardly workable in lower animals. These clinical problems are bound to be of a wide range on account of the representativeness of the clinical material, the drainage-product, namely, of a metropolitan district. German models are available, and articulation with the state system of government carries with it sundry advantages. The juxtaposition of the medical and social points of view

must direct one's progress. Local influences (Massachusetts General Hospital, Boston Dispensary) are of especial advantage. The paucity of sociological and psychological contributions is clearly in evidence. To secure a more even development of psychiatry, these latter should be stimulated, though naturally the somatic studies should not be permitted to lag.

2. Value of the Wassermann Reaction.—W. P. Lucas states that the general usefulness of the reaction is being more and more recognized in cases of so-called latent syphilis or syphilis without manifestations. Many workers use the reaction in cases which give no outward—that is, no clinical—manifestations of disease, but which on examination give the positive Wassermann reaction. The test is useful also in its application to life insurance. When one recognizes the fact that syphilis is a protean disease, and that it has a widespread distribution throughout the whole human race, the value of the reaction in insuring life is seen at once. It is stated that one-third of all syphilitics die early in consequence of their luetic infection. It would be a wise precaution for insurance companies to have all questionable cases tested by this reaction for their own protection, but there are, of course, difficulties in carrying out such measures. In forensic medicine, the importance of the reaction is manifest. It is being used in civil cases as well as in penal cases. The argument that a man is syphilitic can much more easily be made plausible to a judge by the fact that he has a specific reaction than by psychiatric explanations. As studies in eugenics proceed, one becomes more and more convinced that there must be and will be a greater safeguarding of the marriage tie. The infectious stage of syphilis is generally considered to be three or four years; but if the Wassermann reaction is still positive, and if it is true that this indicates spirochete carriers, then one must alter the control of the syphilitic. It seems very probable that this reaction will be used as an aid in deciding the question of marriageability, and that to the present generally accepted rule, which demands treatment over a certain period of years before marriage, will be added the requirement of a negative Wassermann reaction.

4. End Results of Excision of the Knee for Tuberculosis.—R. B. Osgood, in order to compare the end results of the excision of the knee for tuberculosis, in which metal plates or clamps were used to hold the bone ends in close apposition, with the cases of simple excision, traced the twenty-eight excisions for tuberculosis of the knee joint done in his orthopedic service during the last five years. In twelve of these no metals were used to hold the bones in apposition. That is, a simple excision was done, chromic catgut or kangaroo tendon occasionally being used to hold the bones together. In two cases silver wire suture was employed. In fourteen cases aluminum wire clamps or bone plates were used, in eight the aluminum wire clamps devised by Goddu, and in six the malleable iron bone plates suggested by Brackett. The comparative statistics of this small series of cases would seem to show that the holding of the nicely approximated bone ends firmly together has definite advantages. The postoperative pain is less, early union is favored and the only untoward effect which was noted was the occasional necessity for the removal of the bone clamp or plate. This possible eventuality seems of little import when compared to the greater assurance of diminished suffering and quicker return of safe and painless weight-bearing.

10. Food for Babies. M. Alice Asserson.
11. Wounds of the Pericardium and Heart. G. G. Holladay.
12. Acute Mercury Poisoning. J. M. Lobsenz.

1. Animo Nitrogen Content of Syphilitic and Nonsyphilitic Sera.—D. M. Kaplan refers to the usefulness of the amino nitrogen determinations in the sera of cases in which syphilis is suspected or in which a positive Wassermann reaction is contrary to clinical findings. The amount of amino nitrogen in the serum of a syphilitic remains diminished regardless of the negative Wassermann reaction. Whereas the amount of amino nitrogen in the sera of syphilitics is quantitatively diminished in a larger number of instances than in cases in which a positive Wassermann reaction occurs, it is safe to argue against syphilis in cases in which the amino nitrogen is normal and in which there are no clinically suspicious signs of the disease. In these determinations the author perceives a very important method in weeding out unexpected positive Wassermann results.

2. Prevention of Death and Resuscitation.—A. L. Soresi states that in the prevention of death the heart is always the important element to consider, as there can be profound coma or apnea without loss of life. The question is not one of stimulation of the heart as much as of saving its strength. In pneumonia, for instance, death can be prevented if the heart action can be kept up for a few days, the problem here being one of heart action only, because the disease exhausts itself in a few days. The heart is flushed with blood loaded with poisoned products, and while its stimulating and nutritious element is nourishing it poorly and poisoning it, it has to work harder, because of the resistance met from the consolidation of the lung tissue. With these considerations in view, the author has in two cases resorted to direct transfusion of blood into the external jugular vein after having bled the patients, and in another case, to the continuous dropping of physiological salt solution into the external jugular vein. The results were very gratifying, but on account of the limited number of observations no definite conclusions are made. In severe cases of hemorrhage death can be prevented if the direct transfusion of blood, or at times even of saline solution, through the external jugular vein is resorted to in time.

5. High Frequency Cauterization in Prostatic Obstruction.—A. R. Stevens reports two cases of prostatic obstruction which were relieved symptomatically and objectively by high frequency current cauterization of the obstructing portion of the prostate. The residual urine in a case of contracture of the vesical neck was reduced from twenty-six ounces to one and a half; in a middle lobe case, from fourteen ounces to one-half ounce. Both patients tolerated the cystoscope so well that no anesthesia was used. The treatments were conducted in the office, did not interfere with the patient's work, and were not followed by pain or serious bleeding. Probably the D'Arsonval current would accomplish results in such cases more quickly, but one must be cautious to avoid too deep destruction of tissue. With the Oudin current, after these and other experiences, the author would be willing to do more at each sitting; thus requiring fewer cystoscopies. Although there are but two cases reported the patients received such complete relief that it seems that cauterization by the high frequency current must be considered as a possible means of treatment in dealing with certain types of prostatic obstruction.

4. Congenital Stricture of the Prostatic Urethra.—W. H. Jordan describes congenital stricture as an occlusion of the urethra which may occur at three different places: first, at the meatus; second, at the outer limit of the rossa navicularis, and third, at the membranous urethra. None of the text-books describe a stricture of the prostatic portion. Keyes says that stricture in the deep urethra is exceedingly rare; one text-book denies its existence below one-fourth inch from the meatus. Such strictures are caused by inaccurate apposition in the embryo of separately developed sections of the urethra. The stricture is endodermic in origin. Guibe relates an interesting fatal case in which the stricture admitted only a needle. Stricture of the meatus and fossa is quite common and is often overlooked because it gives rise to few, if any, symptoms.

5. Plastic Operation for Ankylosis of the Jaw.—J. B. Murphy reports two cases of ankylosis of the jaw due to cicatricial formations in the cheek following destruction of tissue. He resorted to a method of flap-interposition which is original. It is well known that in all his arthroplasties he has favored the pedicled flap for interposition between the ends of the bones. Therefore, when the first of these two cases of ankylosis of the jaw came under observation he endeavored to secure a pedicled flap for interposition to prevent a recurrence of the ankylosis. The flap in the first case was removed from the hard and soft palate of the patient and consisted of the mucosa and submucosa. It was a pedicled tongue-shaped flap and it was swung outward so as to cover over the denuded bony surface of the upper jaw, which had been formed when the jaws were chiseled apart. The result exceeded the author's expectations. The flap lived and the ankylosis did not recur. The result was so good that he was led to resort to the same procedure in a second case of ankylosis of the jaw.

7. Pericolic Membranes.—D. Cheever presents evidence from the laboratory and operating-room to show that the veil-like pericolic membranes of the type described by Jackson are congenital variations, occurring in at least 10 per cent. of individuals and causing in the majority of instances no symptoms whatever. In the infrequent cases in which there is satisfactory evidence that they constrict and obstruct the function of the colon, they should be divided, preferably with the cautery protected by a spatula introduced beneath the membrane, as advised by Hofmeister. Jackson's recent reported experience in two cases gives one ground to expect that after division they may not form again. The other type of membrane, whose cause is either inflammation spreading from one visceral lesion, or, as the author thinks less likely, peritoneal irritation from intestinal stasis, is more likely to cause symptoms and require operative relief. Further progress in these problems will follow the careful analysis of the symptoms and living pathology of many cases by many observers, and above all the conscientious interpretation of after-results.

8. An Analysis of 35 Consecutive Cases of Bradycardia. C. E. Lea.
9. Medical and Surgical Experience in the Balkan War. C. M. Page.

1. Early Diagnosis and Treatment of Pulmonary Tuberculosis.—J. Mitchell Bruce refers to the diagnostic import of pleurisy. A large proportion of the cases of dry pleurisy or of pleurisy with effusion are followed by pulmonary tuberculosis. Hemoptysis may exist without physical signs, yet in most cases it is indicative of pulmonary tuberculosis. There are cases occasionally met with in which early tuberculosis is masked by bronchial catarrh. In any of the above cases the patient's family history is of diagnostic importance. The maximum of difficulty of diagnosis in early tuberculosis is reached when the only complaint of a delicate looking youth is languor. Early febrile tuberculosis is often confounded with typhoid fever. In discussing the treatment of incipient tuberculosis the author compares the merits of sanatorium and non-sanatorium treatment. In every case of pulmonary tuberculosis there are indications for and against sanatorium treatment. The one set or the other set prevails, and the patient is advised accordingly. The author has to-day two patients belonging to the present series in sanatoriums, the one consequent on hemoptysis, the other because of simple loss of energy and weight and extremely slight pyrexia, both without definite physical signs. But he has more patients of the series doing their best at home, whether with or without attention to work. He has found it impossible to take an only boy of 15 from his wealthy parents. They will go abroad with him to a suitable climate. Another patient lives in an entirely unexceptionable situation under the close observation of his family doctor. A third patient was removed from an office in the city and sent at once to the country to take up an outdoor business. A delicate boy with suspicious or more than suspicious symptoms goes to a school on the coast of Kent, where such lads are specially received and closely watched and cared for. And, finally, one is compelled to compromise in a good many instances in other ways, being able only to insist on strict hygiene in house and office, on early hours, on full advantage being taken of week-ends and of holidays, with abundant food and well-regulated exercise. It is in such cases as these that Lees's method of continuous inhalations of antiseptic solutions would appear to be peculiarly suitable and successful.

2. Solid Tumors of the Umbilicus in Adults.—A. E. Barker notes that although solid umbilical tumors are a rarity, in the experience of one single surgeon or hospital, a considerable number have been put on record and their source of origin, pathology, and structure have been worked out fairly completely. These tumors have the following modes of origin: (1) Malignant growths of the abdominal viscera may become attached to the umbilicus and may grow through it before producing any marked abdominal symptoms. (2) The umbilicus may

be originally or be converted ultimately into a bottle-shaped cavity which may be almost or completely closed, so that a large amount of epithelial débris accumulates within it and forms a concretion or cholesteatoma around which suppuration and great fibrous thickening may occur. (3) Atheromatous tumors derived from sebaceous follicles included in the navel scar may reach considerable size. (4) Adenomata may form from sweat glands included in the scar and reach considerable dimensions and simulate a malignant tumor. (5) Adenomata have been found lined by columnar cells, apparently being formed from remnants of the vitelline duct. (6) Calculi have been formed in remnants of the urachus. (7) Malignant tumors of the navel have been met with in some cases derived from ectodermal structures and in some others from vitelline remnants (columnar epithelium). (8) One has been described by H. Ehrlich which apparently was derived in part from remnants of the vitelline duct and in part from the sweat glands of the umbilical skin. (9) Foreign bodies have been found to lodge in a very hollow umbilicus in fat people and become mixed up with hairs, shreds of clothing, dust, and epithelial débris, and to cause by irritation a large solid inflammatory tumor. (10) Scondary malignant deposits have been found to show themselves in the navel before the primary visceral growth within the abdomen has given any signs of its presence.

4. Nodular Leucemia.—G. R. Ward states that the "associated syndromes" of leucemia are four in number, and with the exception of one, chloroma, are not necessarily a part of leucemia, but may be met with in other conditions. The four "associated syndromes" are as follows: The first is the syndrome in which one finds symmetrical skull tumors, often of a green color, but not always, and resulting in blindness, deafness, etc. There may also be lesions of other bones, or, rather, of the periosteum in other situations. This syndrome has usually been called "chloroma," on account of the green color of the lesions. All cases with a green color and some others are examples of leucemia, but a similar syndrome may arise in suprarenal sarcoma. The green color may be found in the marrow, etc., of cases of leucemia which have no skull lesions, and may be absent in the skull lesions of other undoubted cases of leucemia. Hence the syndrome is unduly limited in one direction and unduly enlarged in another if one regards the green color an integral part of it. The second syndrome is known as the "mycosis fungoides" syndrome. It lacks another name, and hence is properly included as nodular leucemia if a multiplication of names that subsequent research may render quite valueless is to be avoided. In these cases there are a number of nodules either just under the epidermis or in the deeper subcutaneous tissue, and these are very commonly more or less symmetrical in distribution. They may come and go with great rapidity, but this is by no means always the case. A similar syndrome may occur in cases of sarcoma, but the leucemic nodule very rarely, if ever, ulcerates through the skin, whereas the sarcomatous nodule may easily do so. The third syndrome is often described under the name of Mikulicz's disease. It is characterized by swelling of the lacrymal, paratid, and submaxillary glands. The swelling is usually chronic and painless, and does not tend to suppurate. As a matter of fact, this "symmetrical glandular syndrome" is not infrequently of greater extent than would appear, for, besides the glands mentioned, the mammæ, ovaries, or testes may be affected. The swellings are always symmetrical, and microscopically show an infiltration of the gland substance with cells similar to those seen in the blood. The fourth syndrome is that of persistent priapism. This, of course, may be met with in other conditions, but the most common single cause of persistent priapism has been shown by Warthin to be leucemia. This, like the others, is of the nature of an infiltration, although some of the infiltrating cells may multiply *in situ* and give rise to more or less distinct nodules standing out from the surrounding infiltration. If the infiltration itself is too slight to be appreciated clinically the nodules will appear to be the sole lesions.

5. Ectopia Cordis.—W. Rolland states that the cases of ectopia cordis which have been reported are very few. Barnardo records a case in which the child lived for six hours. The subject is very fully discussed by Ballantyne, who gives numerous references to the literature of the subject. Besides referring to cases accompanied by sternal fissure (of which the author's case is an example), he points out that there are two other chief varieties—ectopia suprathoracica, in which the heart is displaced upwards into the neck, and ectopia subthoracica, where there is displacement downwards through the diaphragm into the abdominal cavity or the sac of an exomphalos. A case of the latter variety is recorded by Holt. There seems to be some doubt as to the factors which tend to produce this deformity. Ballantyne suggests arrested development of the thoracic walls as the most likely explanation, and this view is supported by the fact that in some cases amniotic bands have been found attached to the heart and tending to pull it forward out of the thorax.

July 14, 1913.

Pulsus Durus.—Lewinsohn refers to the common belief that a high blood pressure must always be associated with "hard pulse." This is by no means always the case. Out of 100 sphygmograms of "hard pulse" there were no less than 17 in which the blood pressure was not elevated —being in some cases from 90 to 110 and in others from 110 to 130. The age of the patients was from 40 to 65. In the remainder the finds were typical in character, the pulse being hard to the finger, the sphygmogram typical of arteriosclerosis, and the tension of the blood correspondingly high. We now have to explain the 17 cases, of the same general clinical type as the others (arteriosclerosis, cardiac, and renal disease); and the author found in all of them evidences of weakened myocardium, associated either with nephritis or arteriosclerosis. It is probable that originally the blood pressure in these cases had become gradually lower; in other words, compensation had reached its limit.

Vomiting of Gravidæ.—Asch evidently believes that there is something phylogenetic about this phenomenon, and that causes alleged at present are largely secondary. Nausea and vomiting seem to be a part of the instinctive cravings of the primitive woman and especially of instinctive repugnance to certain articles of food. Women are nauseated by tobacco smoke who ordinarily are accustomed to it. The same is true in the case of alcohol and tobacco. All these repugnances make directly for nausea. The normal individual has natural dislikes, which in the case of certain nauseating substances he chooses to overcome. Nausea in the gravida may be noted very soon after conception; and the author tends to blame the maternal nausea upon certain ingesta, the taste for which

has gradually been acquired. He believes that women can be fed so that the nausea may be antagonized. In addition nausea has, as in the normal woman, a reflex origin, not alone from the uterus but from localities like the mucosa of the nose. He has nothing to say of the severe manifestations which often accompany vomiting and refers doubtless to simple vomiting and its direct consequences. He believes it possible to cure this vomiting by physiological means—diet—carried out to great refinements—and the relief of all peripheral sources of reflex irritation. The chief of these is dilatation of the cervix. If this fail it will be easy to terminate the pregnancy by the same resource. He does not think much of the hysterical explanation. Gravidæ are nervous and this nervousness is aggravated by the factors which cause the vomiting. Still he believes in the psychic management.

New Theory of Graves' Disease.—Marinon of Barcelona gives many clinical and experimental data upon which he founds a new idea of thyroid diseases. His conclusions are as follows: Graves' disease is not a hyperthyroidism or dysthyroidism, but instead a mere variety of hypothyroidism. In the clinic Graves' disease may be grafted upon myxedema and results from nonmetabolized iodine. Most authors would, doubtless, explain this double condition by the term dysthyroidism, but beyond the statement that the latter condition is something different the author does not say much concerning it.

Münchener medizinische Wochenschrift.

July 15, 1913.

The Intracutaneous Reaction in Syphilis and Frambesia.—Baermann and Heinemann, writing from the east coast of Sumatra, report at length on the behavior of these two affections toward luetin and its analogous substance framböitin. Their conclusions are as follows: When either of these extracts is injected intracutaneously in a series of cases of manifest or latent syphilis or frambesia, a surely positive reaction results. The percentage of positives increases with the duration of the disease, the limitation of the disease focus and the intensity of the specific treatment. The reaction is due probably to the fact that specific solvent bodies dissolve the injected debris of spirochetes, the resulting freed endotoxins determining the phenomena of inflammatory reaction. The latter is temporarily specific and reciprocally the emulsion of one form of spirochete can produce reaction in the opposite disease. The experiments are still under way. Generally speaking, luetin reactions behave much like tuberculin reactions.

Rectal Temperatures.—Weinert, after extensive experimentation asserts that after extensive muscular activity the greatest rise of temperature is found in the parts most strained. Tissues not involved directly may show no elevation of temperature. Thus in active walking or running the increased warmth of the lower extremities may ascend to the rectum. The axillary temperature in such cases is usually normal. In bedfast patients, therefore, an increase in rectal temperature would have some significance. Conversely in a patient active on his feet an increase of rectal temperature may have no significance.

Exchange of Nutriment in Parabiosis Rats.—Morpuogo and Satta refer to what we already know of this subject, viz., that there is not an absolute mixture of the two bloods, and that each retains some individuality. How this can occur when both partners share precisely the same food, is more or less a mystery, which the author has sought to solve by elaborate experiments. Some of the results are as follows: If one of the parabiosis rats is fed on saccharose it lives and grows; its partner is fed on a mixed diet rich in nitrogen, and naturally thrives. But this cannot be due to a merely equitable diffusion in the blood of the full nutrient ration. There is some admixture, of course, but it does not proceed indefinitely, so that the caloric requirements of the twins are not covered in a way that we can comprehend. Some new nitrogenous substances must be formed to keep up the balance of nutrition and of these, the authors say, we as yet know nothing.

Fibrolysin in Chronic Pneumonia.—Brenner refers to cases of pneumonia in young subjects which do not clear up at the proper time and are notably resistant to treatment. In a patient of this sort, injections were made between the shoulder blades. The shadow in that locality was seen to clear up remarkably within a few days. Patient began to cough and expectorate freely. In this way resolution promptly set in and the author believes that herein is a great advance in medicine.

Deutsche medizinische Wochenschrift.

July 17, 1913.

Etiology of Acute Psychoses.—Weber states that often in so-called functional psychoses one may find a complication of diseases, no single one of which could explain the rapid and fatal brain disturbance. As a rule in such cases an acute injury of an already long damaged brain forms the essential character of the terminal illness. The chronic pre-existent lesion may be free from symptoms. The acute injury may be traumatic, an infection or intoxication, or an affection of the bloodvessels. The chronic conditions, long present, comprise chronic leptomeningitis, foci of vascular sclerosis, which sometimes can only be shown by the microscope. Naturally in some cases these old lesions, the author maintains, do occasion well-marked symptoms.

Generation in Drunkenness.—Näcke takes up this subject, long a favorite with him. The German word *Rausch* is not really drunkenness in our sense. The author speaks of it as a purely relative term, which is exactly the case. In one connection the word corresponds exactly to our "jag" and similar terms suggesting a short, intensive form of alcoholism, which may soon pass off. The *Rausch* produced in a man bears no relationship to the amount of liquor taken. Psychopaths and epileptics are extremely intolerant, as are some normal persons, in stages of great suspense and excitement. Such may act as if under the influence of laughing gas for a few minutes and then come out of the *Rausch* suddenly. It is selfevident that a man with the latter has good control of himself or he would be unequal to the demands of copulation. It is difficult to determine just when the fecundating coitus occurred, and whether one or several acts occurred during a given interval. Matters of forensic importance must also be considered, for example, the exclusion of coitus with other men. Again, if man or woman or both were weakminded it would be unnecessary to invoke the drink as a material factor. We have very little knowledge of the state of the semen of a temperate man when he copulates while alcoholized. Alcohol applied in minimal quantities to living semen does not appear to cause any impairment of activity. The proof in this problem is so difficult that the author hopes much from forthcoming studies on alcoholism.

Syphilis and Neurasthenia.—Krebs concludes that there is a syphilitic neurasthenia in both the acute and chronic stages of the lues. In all neurasthenias with history of syphilitic infection, the Wassermann should be used—first in the blood and with this negative, the lumbal punctate. In positive cases mercury, potassium iodide, and salvarsan should all be exhibited; while to exclude syphilis the patient should go under a regular course of nerve and general treatment—both sedative and stimulating.

Insurance Medicine.

Results of Study of Family Histories.—Dr. H. A. Baker, Medical Director, Pittsburgh Life and Trust Company, in his annual address as Chairman of the Medical Section, American Life Convention, held at Hot Springs, Ark., February, 1913, referred to a paper read by Dr. Symonds before the Association of Medical Directors, in which was shown the effect upon the offspring of different degrees of parental longevity. One hundred and sixty-six thousand family histories were classified under five groups, as follows: Symbol A—Both parents reach 70; Symbol B—One parent and two grandparents reach 70, other parent living; Symbol C—Both parents living below 70 and three grandparents reached 70; Symbol D—All cases between above and E are to be classed as D; Symbol E—Both parents dead below 60. It will be noted that A shows the best family history and E the poorest. The groups were arranged so as to be homogeneous with reference to factors other than family history, all hazardous occupations and medical impairments being excluded and only average weights accepted and included. The expected mortality was calculated by Dr. Symonds as follows: (1) The percentage mortality of A, B, C possessing a good long-lived history, is distinctly good, being 87 per cent. in A, 86 per cent. in B, and 86.5 per cent. in C. (2) D is inferior, the percentage mortality being 92 per cent. D is composed of those with an average family history and contains the largest number of entrants, of whom a certain number have the possibility of a long-lived family history. (3) E shows a percentage mortality of 110 per cent. and is composed of those with a short-lived family history. The difference between a long-lived and a short-lived family history is only ten years in both parents, they being above 70 or below 60, but the latter gives a mortality twenty-three points larger than the former. It is nearly one-quarter better to be born in a long-lived family. (4) The underweight mortality is not very bad, but the deaths are too few in all symbols for any definite deductions. Dr. Symonds further classified his study of family histories with regard to tuberculosis, and showed that the combination of light-weight, young age, and tuberculosis in the family history is productive of a high mortality, and where one or more members of a family have died of tuberculosis the case is helped by longevity among the remaining members. The following factors which influenced are as follows: (1) Age—Usually a tubercular family history has its maximum effect before 30, its influence diminishing rapidly until after 40 it can be practically disregarded unless the family longevity as a whole is impaired. (2) Weight—A tubercular family history is somewhat neutralized below 30 by a weight which is above the average, between 30 and 40 the effect is less pronounced, and after 40 the overweight seems to disregard the tubercular, and unless care is shown in selection, it will increase the mortality beyond the normal. (3) Amount of taint—Generally considered the larger number of cases of tuberculosis in a family, the more apt the increase in mortality, but this is influenced by the longevity of the family as a whole. If that is good, excellent results may be expected, even with a large amount of tuberculosis in the family. If the longevity is average, the mortality results are average, care being taken with regard to weight, and if the longevity is poor and family short-lived, bad results are obtained even with only one or more cases of tuberculosis in the family. (4) Relationship—A tuberculous brother or sister is as influential in affecting mortality as a tuberculous parent. (5) Heredity and infection—These two factors and the effect of environment were not separated in this study. It is a much mooted question as to whether tuberculosis is inherited or only a weakness of constitution. Nevertheless, the fact that a tubercular family history predisposes to tuberculosis, either by inheritance, infection, or environment is well shown. (6) Kind of insurance—The mortality in the life policies is only 107 per cent., in the limited life policies 101 per cent., and in the endowment policies 144 per cent. While the number of deaths is small, it seems large enough to conclude that the offer of an endowment policy does not improve the mortality due to a tubercular family history, particularly below the age of 40. (7) Family longevity—If the family history is long-lived in general, the tubercular taint has but little effect on the mortality, no matter how much the amount of taint. The family longevity being average, the tubercular taint has considerable effect, and if the family is short-lived the mortality is high, whether the parental deaths be due to tuberculosis or other diseases. Dr. Baker says that the work of the medical director is highly specialized, embracing many subjects and much information not coming within the scope of the general practice of medicine. The literature of his work is limited—confined practically to the proceedings of three associations of medical directors, two in the United States and one in England. He suggested that in the meetings all important events in the realm of insurance medicine should be reviewed in the address of the chairman of the section.

Sugar Assimilation Limit.—Feilchenfeld says that von Noorden's conclusions regarding the sugar assimilation limit are as follows: (1) Normal urine should be free from sugar. (2) The assimilation limit varies with the different kinds of sugars. (3) Glycosuria follows the ingestion of more than 120 gm. of lactose; 150-200 gm. of saccharose; 150 gm. of levulose, and 150-200 gm. of glucose. The assimilation limit is higher on a full stomach. (4) The positive reaction appears in about one hour, and lasts from one to three hours. (5) The assimilation limit for starches is very high. A healthy individual can utilize enormous amounts of starchy food. The glucose test is of importance when there is a question of diabetic heredity or in suspected tendency to diabetes. Feichenfeld also states that if the glycosuria from the ingestion of saccharin may be physiological and at most to be regarded as a sign of diminished ability to utilize sugar, the glycosuria following the ingestion of starches on the other hand, must be regarded as a symptom of actual diabetes. A healthy individual can utilize enormous amounts of starchy food. Martius recommends the determination of the assimilation limit in all cases of diabetic heredity. If there is no glucose in the urine after the ingestion of 150 to 200 gm. (normal limit) in a fasting condition heredity may be ignored. Seifert and Müller state that the physiological glycosuria in healthy individuals is only transitory. A positive reaction after the ingestion of 100 gm. of glucose may be considered as alimentary glycosuria. Permanent glycosuria indicates diabetes mellitus.—*Zeitschrift für die gesamte Versicherungs-Wissenschaft*, May, 1913.

Book Reviews.

The Psychology of Insanity. By Bernard Hart, M.D. (London), Lecturer in Psychology, University College Hospital Medical School; Medical Superintendent, Northumberland House Asylum. Cambridge: At the University Press; New York: G. P. Putnam's Sons, 1912.

This is one of the Cambridge Manuals of Science and Literature, a series of books that aim to present the recent developments in science, history, and literature. In describing the psychology of insanity the author discusses the newer teachings which hold that the manifestations of insanity may be studied by means of the scientific method; that these manifestations operate in accordance with definite laws; that insanity is not a bizarre and inexplicable disturbance of the mind, but may be interpreted as readily as the normal mechanism of the mind. It is pointed out that the fundamental factor in the causation of insanity is conflict—the antagonism of painful mental experiences with those that are not painful. In order to avoid this conflict the mind tries to blot out or submerege these painful experiences, which, however, cannot be eradicated and form disturbing complexes or constellations in the mind. These constitute groups of mental phenomena which lie below the threshold of consciousness, but are potent factors in disturbing the physical and mental well-being of the individual. The author ascribes a dominant rôle in the production of conflict to the operation of the "herd instinct," which is concerned with a vast part of the beliefs and conduct of man—beliefs and conduct upon which the herd has set its seal. "It is possible," says Hart, "that the individual who is faced with an intolerable conflict between his primitive instincts, on the one hand, and who has found a refuge by retiring into a world of phantasy and shutting out the world of reality, can only achieve this by dissociating herd instinct from the other primary forces of the mind and refusing to allow it any longer to play a part therein." The author has written a most interesting volume. His style is remarkable for its clearness, a quality that naturally results from a mastery of the subject matter and the possession of distinct concepts.

A Doctor's Table Talk. By James Gregory Mumford, M.D., Lecturer on Surgery in Harvard University, etc. Price $1.25 net. Boston and New York: Houghton-Mifflin Company; Cambridge: The Riverside Press, 1912.

Extracts from this delightful volume have appeared from time to time in the Miscellany column of the Medical Record. The author presents a number of composite studies of medical men, although no actual individuals are portrayed, under the fictitious name of Dr. Primrose, Dr. Ely, Dr. James, Dr. Flaxman, Dr. Consequence, Scholasticus, Scriba, etc. A vein of subtle humor and satire permeate the author's discourses on various phases of medical life. These include the following: The doctor's habitat, doctor and patient, some doctors and their troubles, Dr. Primrose on women, the doctor as a patient. Dr. Primrose on socialism, reflections—Ambrose Paré, hospital talk, reminiscences, and a letter from Scriba to his son.

Medical Men and the Law. A Modern Treatise on the Legal Rights, Duties, and Liabilities of Physicians and Surgeons. By Hugh Emmett Culbertson, of the Ohio and New York Bars; Contributing Editor to the Laning, Ohio, "Encyclopedic Digest," "Notes on the American Decisions and Reports," and many other legal publications. Price $3.00 net. Philadelphia and New York: Lea & Febiger, 1913.

There can be little doubt that most physicians lack an adequate knowledge of their legal rights and obligations, which deficiency is often a matter of embarrassment if not of pecuniary loss. Although many works have been written on the subject of medical jurisprudence, it is remarkable that none has been written with a view of providing an exhaustive survey of the modern law pertaining to physicians and surgeons. This aim is admirably fulfilled in the present volume, the author of which is peculiarly fitted by training and editorial experience to stamp his work with the seal of authority. A summary of the table of contents will give an idea of the scope of this work. Following an introductory chapter, the author presents in Chapter II a series of definitions. In Chapter III he discusses the statutes regulating the practice of medicine. Chapter IV deals with the relation of physician to patient. The important subject of compensation is exhaustively treated in Chapter V. Chapter VI takes up malpractice or negligence, and Chapter VII discusses the criminal liability of physicians and surgeons. Exemptions of physicians and surgeons are dealt with in Chapter VIII. In the following chapter the author discusses the subject of physicians and surgeons as witnesses. The remaining chapters deal with the right to protect professional reputation, with the validity of contract restricting exercise of profession, and with wills. The author cites the judicial decisions in all of his important statements. An enormous amount of material has been gathered in this volume, which goes into the minutest phases of the legal interests and aspects of medical practice. Among these may be mentioned the validity of gifts from patient to physician, liability for compensation, negligence of partner, privileged communications, etc. The book is well written, in a style that has not sacrificed clearness to brevity. It should prove a useful and almost indispensable addition to the practitioner's library.

Analyse des Harns. Zum Gebrauch für Mediziner, Chemiker, und Pharmazeuten. Zugleich elfte Auflage von Neubauer-Huppert's Lehrbuch. Bearbeit von A. Ellinger, Königsberg; H. Eppinger, Wien; F. Falk, Wien: F. N. Schulz, Jena; K. Spiro, Strassburg i. E.; und W. Wiechowski, Wien. Zweite Hälfte. Mit Textabbildungen, 6 lithographischen Tafeln und einer Logarithmentafel. Price, Marks 27. Wiesbaden: C. W. Kreidels, 1913.

In discussing the first volume of this work, on its appearance a considerable time ago, enough was said in its praise to make further commendation of the completed treatise unnecessary at the present time. While it is termed the eleventh edition of the classical Neubauer-Huppert textbook, the collaborators have so remodeled and rewritten it as to make it in all essentials a new work. The present volume of almost one thousand pages is devoted to the nitrogen, sulphur, and aromatic compounds, the purin bodies, nuclein compounds, the proteids, the urinary pigments, accidental components, enzymes, and sediments. The appendix contains sections on the agglutinins and lysins, some methods omitted in the body of the work, and tables of logarithms, etc., useful in chemical calculations. As it now stands this manual is undoubtedly the most complete work of reference on the urine and one which no scientific worker in this field can dispense with.

A Course in Normal Histology. A Guide for Practical Instruction in Histology and Microscopic Anatomy. By Rudolf Krause, A. O. Professor of Anatomy at the University of Berlin. Translation from the German by Philipp J. R. Schmahl, M.D., New York. With 30 illustrations in text and 208 colored pictures arranged on 98 plates after the original drawings. Parts I and II. New York: Rebman Company.

One of the most valuable textbooks on normal histology which has appeared in Germany in recent years is that by Rudolf Krause, and, fortunately, the volume has now been put into English so that it is available for those who could not consult the work in the original. While the introductory portion on technique, the use of the microscope, embedding, staining, etc., follows the regular lines, the special portion, which is really a descriptive text accompanying the ninety-eight plates, is the part in which the originality and skill of the author are best shown. Beginning with a general section on the cell, there follow chapters on epithelium, connective, cartilage, muscle, and nerve tissue, and the blood. The remainder of the volume is devoted to the microscopic anatomy of the different organs. Each section is numbered and refers to a particular plate, of which the magnification is given as well as the method of sectioning and staining, so that the whole forms a practical laboratory guide to histology. The plates themselves are remarkable for their beauty of color and accuracy of drawing. They have been reproduced by half-tone process and are superior to anything of the kind which has appeared heretofore. The translation, however, has evidently been done by some one not altogether familiar with the subject, and occasionally actual errors have occurred which should be corrected in another edition. One of these at least is rather important. Any one who attempts to bleach pigment cells with a mixture of oxalic acid and sulphide of potassium will not be popular in a laboratory. What is meant, of course, is potassium sulphite. For some unexplained reason, too, the publishers have elected to bind the two parts in separate volumes. This is quite unnecessary, as the portion on technique amounts to only eighty-six pages, and it would have been better to have followed the German edition and combine it with the atlas in one volume. The book can hardly fail to be generally adopted by classes in normal histology.

Building a Profitable Practice. Being a Text-Book on Medical Economics. By Thomas F. Reilly, M.S., M.D., Professor of Applied Therapeutics, Medical Department Fordham University, New York City. Philadelphia and London: J. B. Lippincott Company, 1913.

There can be no doubt that this book supplies a distinct want in medical literature. The young practitioner has little to guide him in the actual practice of his profession apart from the scientific knowledge that he has acquired in medical school and hospital. The economic aspects of medicine must be learned, unfortunately, after years of painful experience. This book aims to acquaint the young physician with those extra-scientific aids to success which the practitioner of former days learned partly from his preceptor and which have been all but ignored in modern medical education. An idea of the scope of this volume may be gained by an enumeration of the chapter headings which are as follows: the economics of medicine, post-graduate study, the hospital and dispensary service, State Board examinations and licenses, location, the office, extra-practice sources of income, the start in practice, medical societies, the office call, first visit, medical finance, collections, bookkeeping, the law and the doctor, professional ethics, advertising, commissions, consultating and consultant, certificates, prognosis, errors in practice, dispensing, religious rites, obstetric cases and emergencies, abortion, the doctor as a specialist, automobile vs. horse and carriage, on drugs and the pharmacist, building up an office practice, aids in practice, on making friends, personal manners, personal appearance, marriage, don'ts in practice, answers to patients, and your life work. This book is plain spoken, one might say, to a fault. There are many devices, and methods, in the practice of medicine, tricks of the trade, as it were, which when put on paper do not look as well as they usually appear when spoken of *entre nous*. Nevertheless the author can justify his frankness on the basis of the fierce economic struggle that spells defeat in the case of so many practitioners of the present day. One may however question the propriety of advice such as the following: "Never have the attendant say that you are at a theater, place of amusement, ball game, etc. You are always out on a call or business." Most people nowadays will vouchsafe to the practitioner at least a little recreation, and the young physician should be advised not to visit places of amusement too often, rather than be told to practice deception. Candor, sincerity, strict attention to one's work, are qualities that make for success, and cannot be replaced by any degree of dissimulation, the counterfeit nature of which will not long be concealed. The gift of humor as well as sound common sense pervades the chapter on marriage. He who has not yet entered the blissful state may have an opportunity of heeding the injunctions: "Beware of marrying any young frivolous school girl with poetic aspirations; rather marry one who will be able to do her own housework for a few years. Trained nurses make good doctors' wives. He who marries money often earns it. Beware of a jealous person in the shape of a wife." The quintessence of wisdom is contained in this admonition: "Don't allow your wife, or anybody else, to come unannounced into the office during a consultation. Don't have the doors open so she can hear."

Klinische Beiträge: Beiträge zur Klinik der Infektionskrankheiten und zur Immunitätsforschung (mit Ausschluss der Tuberkulose). Herausgegeben von Professor Dr. L. Brauer, ärztlichem Director des Allgemeinen Krankenhauses Hamburg-Eppendorf. Redaktion: Für die Originale: Dr. H. Schottmüller (klinischer und bakteriologischer Teil); Dr. H. Much (immunitätswissenschaftlicher Teil), beide am Allgemeinen Krankenhaus Hamburg-Eppendorf. Für die Ergebuisse: Dr. H. Lüdke, in Würzburg. 1. Band, 1. Heft; Einzelpreis, Mk. 9. 1. Band, 2. Heft; Einzelpreis, Mk. 9. Preis für den Band, Mk. 20. Würzburg: Verlag von Kurt Kabitzsch, 1912, 1913.

One cannot fail to grant a cordial welcome to this new addition to the already extensive and almost bewildering periodical literature of medicine. The title of this publication is "Clinical Contributions: Contributions to the Clinic of Infectious Diseases and Immunity Research (with the Exception of Tuberculosis)." The new periodical will form a companion to the already well known "Contributions to the Clinic of Tuberculosis," both having the common main title, "Clinical Contributions." The purpose of the new publication is to provide a comprehensive survey of the progress in the domain of infectious diseases and immunity. This is afforded by a series of collective reviews of the literature. In addition there are original articles presenting important clinical contributions of real practical value. An idea of the scope of this new publication may be gained by a summary of the contents of the two numbers of the first volume which have just appeared. The first number contains the following: "Orthocrasia, Dyscrasia, Idiosyncrasy, Eucrasia, and Anaphylaxis," by E. von Behring; "The Prevention of the Transmission of Acute Infectious Diseases in Hospitals," by A. Schlossmann; "On Herpetic Fever," by Schottmüller; "On Fat Antibodies and their Significance, with Special Reference to Leprosy," by H. Much; "On the Duration of Passive Immunity," by H. Lüdke and D. Orudschiew. The "Reviews" include the following: "The Etiology of Puerperal Fever," by F. Fromme; and "The Neurophile Leucocytes and Their Blood Picture, as well as Their Significance with Reference to the Physiology and Pathology of the Blood," by Arneth. The second number contains the following: "Diseases of the Sublingual Glands, Resembling Mumps," by C. Hegler; "New Discoveries in Tropical Frambesia," by B. Hannes; "The Demonstration of Materials Foreign to the Blood by Means of Dialysis and the Optical Method, and the Employment of this Method with Observations upon it Relating to the Domain of Pathology," by E. Abderhalden; "Contributions to the Serological Diagnosis of Cancer," by E. Leschke; "On the Regeneration of Renal Epithelium in Diphtheria," by H. Hässner; "On Bacteriemia in Abortion and its Clinical and Theoretical Significance," by C. Römer. The "Reviews" include the following: "On Mixed and Secondary Infections," by H. Lüdke; "Anaphylaxis in Acute Exanthemata with Special Reference to the Peptone Question," by H. Uffenheimer and J. Awerbuch. There is also a reply by von Schilling to Arneth's article in the first number on the neutrophile leucocytes. One of the striking features of this periodical is the excellence of the illustrations. Thus Schottmüller's article on herpetic fever is illustrated with ten superb stereoscopic plates, and three other full-page plates, two of which are colored.

The Milk Supply of New York City and its Control by the Department of Health. By Ernst J. Lederle, Ph.D., Commissioner of Health, and Russell Raynor, chief of the Division of Food Inspection. Monograph Series No. 5, of the Department of Health of the City of New York, September, 1912.

This monograph includes a paper read by Health Commissioner Lederle before the last international hygienic congress, on the sanitary control of local milk supplies through local efficient agencies. It also discusses the following topics: Milk and its properties; the milk supply of New York City; the development of milk inspection; rules and regulations of the Department of Health relating to the sale of milk, country milk inspection, city milk inspection, and the control of typhoid fever. There are a number of illustrations, including approved plans of creameries, charts, permits, and photographs showing methods of inspection, model milk stores, etc. This monograph should prove useful to health officers and to all others who are interested in the subject of a sanitary milk supply.

Clinique et Thérapeutique Obstetricales du Praticien. Par P. Rudaux, Accoucheur des Hôpitaux de Paris; avec la collaboration de A. Grosse, Professeur suppléant d'accouchements à l'Ecole de Médecine de Nantes; et V. Le Lorier, Ancien Chef de Clinique d'Accouchements à la Faculté de Médecine de Paris. Price 8 francs. Paris: Vigot Frères, 1913.

This work deals almost exclusively with the subjects of obstetrical diagnosis and treatment. Each topic is taken up in alphabetical order, thus facilitating reference. The first subject discussed is normal labor; then comes induced premature labor; and so on, through anesthesia in obstetrics, appendicitis, and the puerperium, anteversion and the gravid uterus, gestational autointoxication, gestational arthropathies, abortion, baths, cardiopathies and the puerperium, dacryocystitis of the newborn, etc. The wide scope of this work is indicated in the ample selection of topics pertaining to obstetrics and related subjects. Uterine malformations, sclerema, puerperal psychoses, wet nurses, gavage, cystitis, the cradle, fetal putrefaction, vaginitis during pregnancy, syphilis and pregnancy, are topics selected at random that give one an idea of the comprehensive character of this work. The subject of therapeutics is given full emphasis, as may be noted in the large numbers of useful prescriptions interspersed through the text. Obstetrics is a subject that has reached a high degree of development in France, and a book of this kind cannot fail to be of distinct service to the obstetrician and general practitioner.

Society Reports.

BRITISH MEDICAL ASSOCIATION.

Eighty-First Annual Meeting, Held at Brighton, July 18-25, 1913.

(Special Report to the MEDICAL RECORD.)

REPRESENTATIVE MEETING.

The meeting of the representatives which precedes that of the association proper was opened on the 18th and the first of its four special days was largely devoted to official and formal business and to the internal government of the society. It is to be remembered, however, that this representative body can only be regarded as consultative. It consists of some 150 to 200 persons who are delegates only from their branches. They can vote only in the way they have been instructed to do, so that however valuable their discussions may prove, they have no influence on the voting. It is not surprising, therefore, that the constitution is giving some dissatisfaction. At present the association is a limited company—has been so since 1867 when it was registered as such and licensed to dispense with the word limited as being formed for purposes so privileged under the act, such as religion, charity, science, art, and not for profits or paying dividends. Some parties have sought to obtain more powers and for this purpose an attempt was made to gain a Royal charter but the application was refuted. To set the association on a broader basis and enable it to engage in various undertakings, it was next proposed to dissolve the company and form a new one. This matter was discussed at the meeting of the representatives on Friday and they are reported to have formed the conclusion that the cost which would be incurred by that course could hardly be justified in the present state of the funds. This is in accordance with a report of the executive.

In the afternoon there was no little to be said as to whether these representatives should be, as now, merely delegates or should vote according to their own views. It has frequently been found that they have been obliged to vote as directed by their senders although they have spoken in the opposite direction. Last year in the contest with the government about the insurance act the obligation to vote in a special way was found to be inconvenient and sometimes involved absurdity. The meeting concluded that the by-laws did not work well, and as that coincides with the views of the executive and probably with a majority of the members it is likely that means will be found to effect a change.

First Day—Friday, July 18.

The representatives met in the town hall of Hove, which is the united twin of Brighton. They were received by the mayor of Hove in full civic robes and attended by the mace bearer.

A special welcome was also extended to the meeting by the local division of the association, which through their chairman, Alderman Dr. Gervis, J. P., presented a set of hour or rather minute glasses mounted in silver. By using these a chairman can regulate the length of speeches as he pleases to 10, 6, 5, or 3 minutes. As the sand runs out there is a ring which shows only 1 minute left, so the speaker may take warning that he must shortly close and the chairman may, if he thinks well, ring a little bell. The gift was accepted with cordial thanks and there are not wanting those who hope its use will not be confined to the representatives' meetings. For that is nominally a secret conclave though it is not very difficult to find out what passes in the ordinary way.

Last year a number of addresses were given during the meeting on alcohol and its effects on the body. This year the plan is to be extended. Brighton, Hove, Eastbourne, and other coast towns and the neighboring villages are to be favored with addresses, as many as thirty-seven being arranged for. The representatives dined together in the evening.

Second Day—Saturday, July 19.

The fear that one of the amendments to the insurance act proposed in the House of Commons would have the effect of giving the approved societies the administration of medical benefit was fully discussed on this day and the following resolution passed: "That this meeting strongly protests against the amendment to the national insurance act, proposed by Mr. G. Locker-Lampson, having for its object the transference of the administration of medical benefit to approved societies, which would be a distinct breach of faith between Parliament and the medical profession, and will, in the interests of the public and the profession, offer the most strenuous opposition to this or any other attempt of the kind."

There is no doubt that this proposal has brought together in opposition a great number of practitioners both those on the panel and those who are not. Copies were ordered to be sent to the Prime Minister, the Chancellor of the Exchequer, the joint insurance committee, and others. The meeting seemed determined to adopt every possible way of opposing the proposal. They will probably be supported by the whole profession and if the politicians force it through the medical war with the chancellor and the government is likely to break out afresh; for an immense majority who went on the panel were induced to do so by the prospect of being rid of interference by the clubs.

The standing orders were suspended and as a matter of special urgency leave was given to the delegates of St. Marylebone and Chelsea to call attention to and move a resolution expressing "disapproval of any action which might seem to condone the methods used by the government in bringing the insurance act into operation." This was carried almost unanimously, one or two refraining from voting and no little enthusiasm prevailed. It was directed against an invitation by those arranging for the section of medical sociology, to Mr. Lloyd George and Mr. Masterman to be present and take part. The former's engagements prevented acceptance and probably the latter will find an excuse though it is said that at first he hoped to be present. The representatives seem to think this resolution of great importance as showing that the insults heaped on the profession and the unscrupulous measures for inducing men to join the panels ought not to be condoned.

Third Day—Monday, July 21.

The proposal to register the association as a trade union or to encourage the formation of a separate society in connection with or under the control of this organization gave rise to a warm discussion. Those favoring such a plan said registration under the trade union acts would confer immunity for the funds and disciplinary powers over the members wider than could be exercised by a voluntary association. Both these views were disputed and the latter if true was said to be most undesirable. A resolution was proposed favoring some such change and at once met by an amendment, thus putting the discussion in order for obtaining the prevailing opinion. It was mentioned that there is in existence the "Medical Guild" which is duly registered. Last year the proposal was considered and abandoned on account of the danger of doing anything outside the articles of association, in which case the Charity Commissioners might interfere and take charge of the funds. Other objections urged were that medical work was not adapted for regulation by trade union methods and a profession could not resort to such methods which were usually worked by large groups of fellow workers, whereas medical men are scattered as individuals and would disdain the weapons of the workman.

There was some question of rescinding the resolution come to some months ago, asserting that it was derogatory for the profession to serve on the panels or aid the administration of the act. It appeared to be recognized that the possibility of ending the act no longer existed and mending it must only occupy their attention. But the objection to it seemed no less and it can hardly be thought that such should be the case while it was determined to exercise every possible influence to compel exhaustive amendments.

The difficulty arising from some Welsh societies which have attempted to reconstitute contract practice under the clause authorizing certain insured persons to make their own arrangement was also considered and a compromise was effected providing that in every case of such arrangement the essence of the contract between doctor and patient should be only of an individual character. In fact, here and everywhere it was held that whatever difficulties might be propounded every patient should be entitled to choose his doctor as freely as under the old system. Prolonged consideration was also given to other points, as the relation of the payments of uninsured and insured persons of the same class. Strong objection was expressed to any contract being set up for midwifery cases. It was held that district insurance committees should have the same proportion of medical members as the county insurance committees.

Fourth Day—Tuesday, July 22.

The representative body held a further meeting this morning and first of all confirmed by a large majority on the resolution itself, the decision of the previous day on the amendment rejecting the proposal as to trade union. They next considered the other points of the scheme of the State Sickmen Insurance Committee which proposed

to raise a fund for defence to contribute to certain local expenses, to organize the divisions, to pay members for certain services to the association, and so on. It was reckoned that a subscription of £5 from 5,000 members would suffice for the scheme. Those opposed to it contended that such a plan could not succeed on a voluntary basis and as the trade union part of it was rejected it might as well be given up. After debate it was agreed to refer the matter to the divisions and that a special meeting of the representatives should be held later on to decide on this and other points which must crop up as the agreements under the insurance acts will expire early next year.

To the special representative meeting thus determined on was also referred the question of raising the subscription from 25 to 42 shillings, with a recommendation in favor of this course. Those supporting it urged that lack of funds has been a standing difficulty, that it was a great hindrance in the contest with the government and that it is estimated that the deficit for the year with be £5,600.

It seems likely enough that the increase will be adopted but whether that will reduce the list of members remains to be seen.

GENERAL SESSIONS.

First Day—Tuesday, July 22.

The annual general meeting of the association itself, as distinguished from the subsidiary representative meetings, held in advance, was formally opened on Tuesday, the retiring president, Sir James Barr, in the chair. He remarked that his year of office had been a fighting year. That was not with the outside only, for some medical men seemed to think a president had no right to have any opinions. That idea was very prevalent with Mr. Lloyd George's supporters and they threatened him because a year ago he described the insurance act as a fraud on the public. He still held that view. Out of an act costing seven or eight millions the doctors only got five or six and they did all the work—obviously an unfair distribution. Sir James then introduced to the chair his successor, Dr. William Ainslie Hollis.

A vote of thanks for his services was accorded to Sir J. Barr, who briefly acknowledged the honor. The president-elect was then formally introduced by Sir Alexander Ogston of Aberdeen, where next year's meeting is to be held. Sir A. Ogston is surgeon to the King for Scotland and was in similar office to Queen Victoria and King Edward. He is consulting surgeon to the infirmary in Aberdeen and emeritus professor in the university.

The adjourned general meeting was held in the evening, Dr. Hollis presiding. The mayor of Brighton attended to offer a welcome on the part of the town, which he said considered itself as a camp follower of the health army to which the association belonged. Indeed, he reminded them there was high literary authority for claiming to be one of them under the title of "Dr. Brighton" and they were very desirous that the high status of their profession should be maintained.

Thanks to the mayor for his reception and cordial speech having been duly honored, the energetic local honorary secretary, Dr. L. H. Parry, on behalf of the division, presented to Dr. Hollis a replica of the presidential badge, expressing at the same time the hope that his year of office would be most prosperous for the association and the sincere wishes of his fellow townsmen for his personal happiness. The badge was hung round the neck of Mrs. Hollis amid the vociferous applause of the assembly and Dr. Hollis expressed great gratitude for the honor done him and the manner in which the association had greeted his election.

Dr. Parry then introduced foreign visitors and colonial delegates. Dr. T. J. Verrall, chairman of the representatives, presented on behalf of the council, the gold medal of the association to Dr. J. A. Macdonald in recognition of special services extending over a number of years. Dr. Macdonald found it difficult to express adequately his appreciation and could only say in all humility, "thank you."

That the presentation was popular was clearly shown, for the assembly struck up "for he's a jolly good fellow."

The president then presented to Mr. William Leonard Braddon, F.R.C.S., the Stewart prize of £50, which was instituted by the late Dr. Alexander Patrick Stewart, for good research work in epidermiology. It is now presented annually from the fund.

Then came the chief incident of the evening meeting.

President's Address.—On rising to deliver it Dr. William Ainslie Hollis was received with great enthusiasm by the crowded audience. He announced his subject as "The Medical History of Brighton and the Neighborhood." He suggested that if presidential addresses were generally devoted to the results of research into the medical history of the places visited they would in time make an extremely interesting topographical account of English medicine.

Dealing with the prehistoric epoch as it affected Brighton he made a passing reference to the discovery of the Piltdown skull, and then considered the bearing on his subject of the neolithic remains discovered near Brighton. Many of the so-called pygmy flints, with their sharp edges and needle-like points, would make very respectable lancets for the modern general practitioner, and with what was known of the cleverness of the Stone Age surgeon, of his skill in the treatment of fractures and of his ability to trephine the skull of his patient, it was very probable that some of the flakes might have been used for trepanning, blooding, tattooing, or shaving. In a case in the Valley of the Wye a fragment of human bone had recently been discovered, probably of neolithic date, and in it were distinct indications of an operation having been performed during life. After the Norman Conquest, when the overlords were compelled to look after the health and general welfare of the villeins, the monks of the rich Cluniac Priory of St. Pancreas at Lewes built at the beginning of the Thirteenth Century an infirmary for the sick and infirm. During the late Tudors there was apparently so great a dearth of qualified medical men that the sanitary welfare of the bulk of the people was in the hands of a group of ignorant and unscrupulous charlatans. With a view of increasing the supply of doctors a Statute was passed in the third year of Henry VIII, improving their social status, giving them a right to sue the illegal practitioner and mulct him in a fine of £8 a month and releasing him from jury service and carrying arms. Shortly after the middle of the Eighteenth Century Dr. Richard Russel, Physician to St. Thomas's Hospital, discovered Brighton and wrote an essay on treatment by sea water. Of this essay his contemporary, Dr. Speed, wrote: "I think we ought to attribute the alleviation to the prudent use of other select medicines which this author employed rather than to the drinking of sea water." The President referred to the prevalence of rabies at this period, to the advances in surgery, with the practice of trephining for fracture of the skull, and the extensive use of bleeding. Even then, however, professional opinion was by no means unanimous as regarded the value of the latter operation. In illustration of this point he described how a distinguished nobleman lay ill, and the disciples of Galen, who had assembled at the bedside, could not agree as to the necessity of bleeding the patient. At last one of the doctors said he had a butcher ill with similar symptoms. "Suppose I go and order him to be let blood immediately. Then by to-morrow we shall know the result." Next day the medical council met early to hear the report of their colleague, who hastened into the room vehemently exclaiming, "No bleeding, no bleeding, the butcher is dead!" At the commencement of the Nineteenth Century Brighton became the happy hunting ground of charlatans and medical knights errant, and fashionable beauty in distress was much exploited. The induction of a sudden change in atmospheric pressure over a painful joint or within a hollow viscus was a favorite mode of treatment, and was used as a remedy for gout among other diseases. Teddy Palmer, a Brighton blacksmith, conceived a method of treatment by medicated air, by means of which he cured the Regent of a toothache. In conclusion, the President referred to the address delivered by his predecessor in the chair in Brighton, Dr. W. W. Moore, in 1886. Dr. Moore had taken as the subject of his presidential address "The Higher Education of Women." His conclusion could be gathered from the following quotation: "I think that it is not for the good of the human race . . . that women should be freed from the restraints which law and custom have imposed upon them, and should receive an education intended to prepare them for the exercise of brain power in competition with men." He should be sorry to endorse those words as the considered policy of the President of the Association. As regarded the great sex question, public opinion had changed during the last seven and twenty years, and women looked upon the question from a different viewpoint to that they then held. The British Medical Association had always welcomed lady diplomats in medicine, and it had extended to all its members equal privileges, regardless of sex. He trusted that that truly democratic spirit would always pervade its policy.

Second Day—Wednesday, July 23.

The Council met at 9 A. M. Wednesday morning and

the several sections at 10. Groups of the representatives and others were to be found discussing with no slight vigor. The Insurance Act and the various amendments proposed. That of Mr. Locker-Lampoon in the House of Commons was generally condemned as nothing less than handing over the control of the medical benefit to the approved societies which was in direct contradiction to the spirit of the act and opposition to the association. In fact it is regarded as restoring contract practice in a more intolerable form than before. There was a large audience at the Royal Pavilion in the middle of the day to hear the

Address in Medicine.—This was given by Professor GEORGE R. MURRAY, M.D., D.C.L., of the Manchester Royal Infirmary. He took for subject "Some Aspects of Internal Secretion in Disease." He showed the great increase of our knowledge of the ductless glands during the last 25 years. Bernard regarded all products passing into the blood as internal secretions but we now reserve the term for useful products of the activity of certain glandular cells which play a definite part in metabolism. He described the disorders associated with ductless glands and the extent to which gland extracts have been introduced for their relief. It is now recognized that ductless glands have important relationship to one another. The secretion of one may either stimulate or inhibit the activity of others. His own attention was drawn to this aspect by two cases observed 17 years ago. So far we can only recognize well marked maladies due to abnormal ebb and flow of internal secretions or marked changes in structure and function of these glands. Perhaps less definite forms of ill health may arise from minor changes of the kind. But we still desire to discover the means of supplying deficient or increasing activity of these organs. In the afternoon there was a picturesque procession from the pavilion grounds to the parish church where a special service was held. A large number of visitors went to a garden party and other groups visited the various sights of Brighton. In the evening the mayor gave a reception followed by a dance in the dome.

Third Day—Thursday, July 24.
